  - Flares
  - Stars

## Testing Kerr hypothesis with SMBH?

- $\star$ BH are better: curvature is higher
  - EFT coupling cst *very* weak if relevant scale is Planck
  - Does it make any sense?
- 
- Strong-field GR is poorly tested: use all available probes!
  - BHs are reasonable places to look for GR failure
  - Uniqueness theorem can break in non-GR: SMBH  $\neq$   $\star$ BH?
  - Compact objects *very different from* BH
  - The relevant scale of GR breaking might not be Planck
  - $\rightarrow$  *Very relevant to check as much as we can!*

## Critical curve

- **Spherical photon orbits** = Kerr bound null geodesics
- Its image = **Critical curve**, dictated by **gravity only**
- not observable! *Mathematical locus* on sky

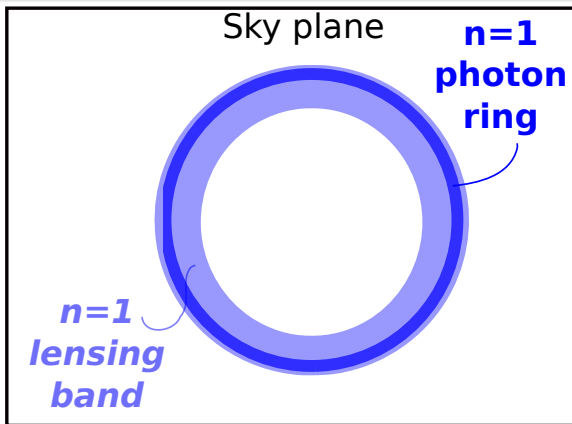

## Lensing bands

- Locus on sky of geodesics that make  $n$  half turns:  
**lensing bands**  $\rightarrow$  *nearly-bound* Kerr null geodesics
- Again not observable!
- No emission for the time being! Just shooting geodesics

### Adding astrophysics: emitting region

- Sequence of lensed images contained in lensing bands
- For each band, *some* part contains *some* flux
- These images are the (astro-dependent) observables

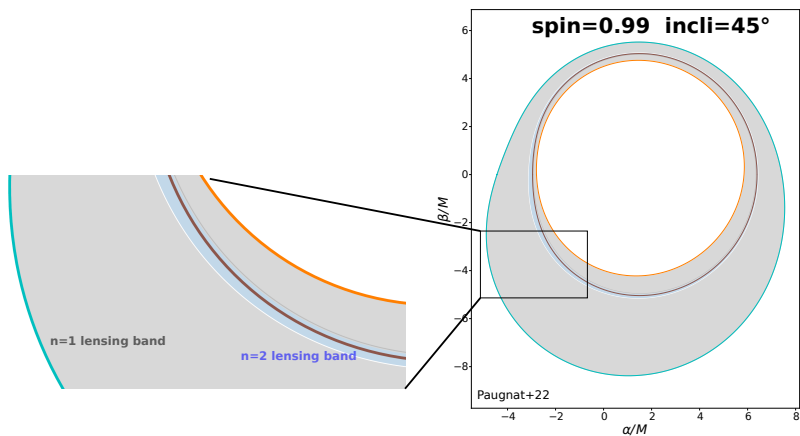

## Photon rings

- Bright part of lensing band = **photon rings** = *observable*
- Infinite sequence of such rings
- Depends on **gravity + astro**

## Photon rings

- Bright part of lensing band = **photon rings** = *observable*
- Infinite sequence of such rings
- Depends on **gravity + astro**

## Lensing bands in real life

## Photon rings in real life

- Rather thin stuff to detect!

## Photon ring conditions

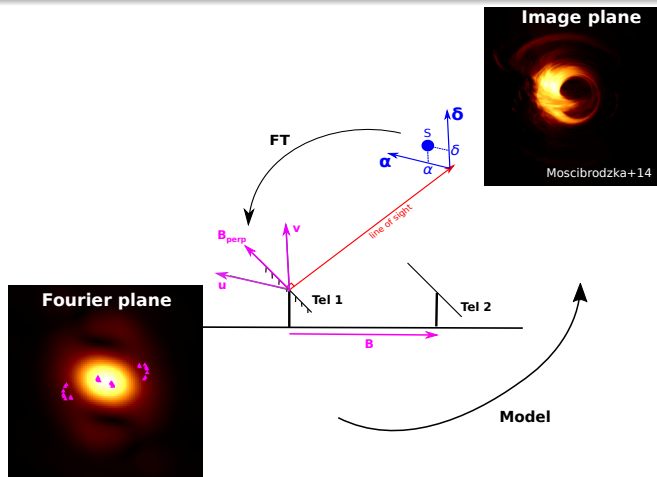

- Optically thin
- Localized emission (disk, jet, blob; not spherical shell)
- → rather generic!

## Photon ring properties

- Logarithmic divergence of intensity close to critical curve
- Exponential convergence to critical curve, and decreasing ring width:  $w_{n+1} = e^{-\gamma} w_n$ ,  $\gamma = \text{Lyapunov exponent}$

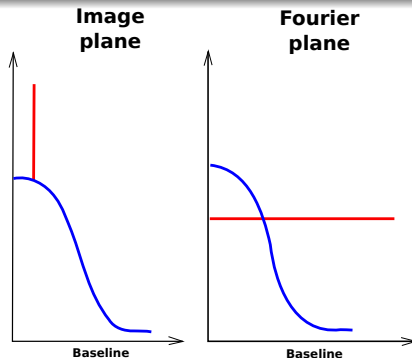

- See Johnson+20, Gralla & Lupsasca 20, Paugnat+22, Lupsasca+24 ([arxiv:2402.01290](https://arxiv.org/abs/2402.01290))

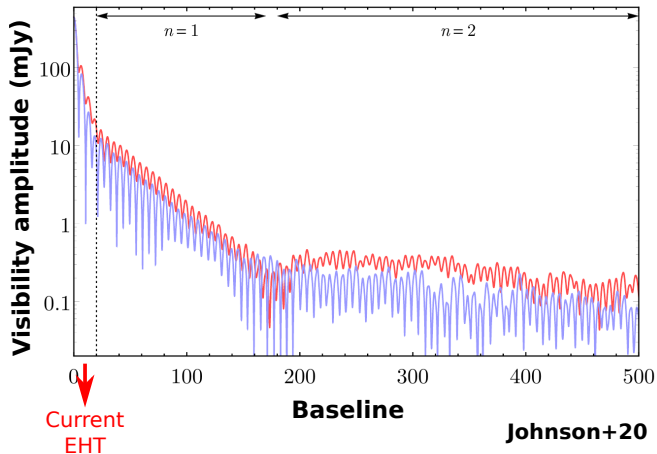

## Observable

- Complex visibility: FT of image
- Sampled by interferometry

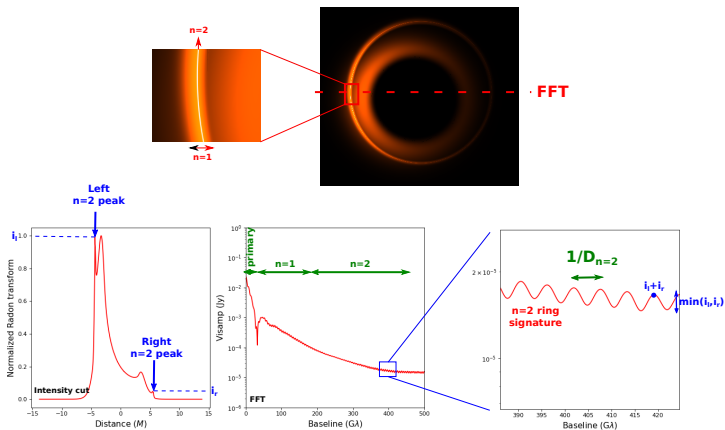

## Detecting sharp features (photon ring!)

- Image = Gaussian + Dirac
- FT = Gaussian + constant
- The sharper in image plane, the further you survive in Fourier freq
- So **sharp feature should dominate at high Fourier freq!**

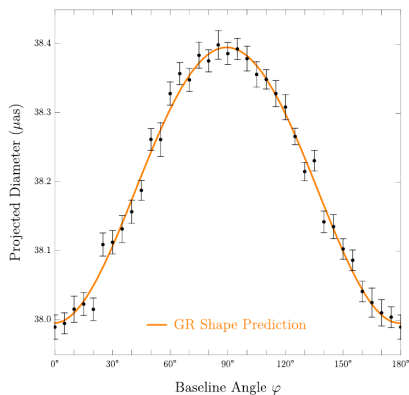

## Photon ring visibility signature

- Various rings dominate at higher and higher freq

## Photon rings diameters

- Measure  $D_n \rightarrow$  Kerr test??

## Gralla, Lupsasca, Marrone, 2020

- $d(\varphi) \rightarrow$  astro-independent shape in Kerr (*circclipse*)
- “Universal observable property” of  $n = 2$  photon ring
- Kerr test!

## What kind of test?

- **Consistency** test: what we observe is in agreement with Kerr (but likely with many other things as well)
- **Discriminatory** test: what we observe is more in agreement with Kerr (Bayesian meaning) than with alternatives

## Caveat!

- **Degeneracy** astro/geometry: a discriminatory test should be sure to break it
- “Theory A + Astro model B” can lead to same observables as “Theory B + Astro model A”...
- Very difficult given our poor knowledge of the flow

## 29 May 1919 solar eclipse "Eddington experiment": an example of a discriminatory test

*The Times,*  
7 Nov 1919

## What kind of test?

- **Consistency** test: what we observe is in agreement with Kerr (but likely with many other things as well)
- **Discriminatory** test: what we observe is more in agreement with Kerr (Bayesian meaning) than with alternatives

## Caveat!

- **Degeneracy** astro/geometry: a discriminatory test should be sure to break it
- “Theory A + Astro model B” can lead to same observables as “Theory B + Astro model A”...
- Very difficult given our poor knowledge of the flow

## Gralla+21, PRD, 103, 024023

- No test of GR with EHT; astro uncertainties

## EHT6 on SgrA\*, ApJ, 925, 119 (2022)

- Discuss  $\alpha_1 = d_{\text{ring}}/d_{\text{crit}}$ ; testing what?

## Bauer+22, ApJ, 925, 119

- Departure to GR (parametric) leads to very weak features ( $\ll$  astro)

## Staelens+23, PRD, 107, 124026

- Lyapunov exponent (width ratio) better probe than shape

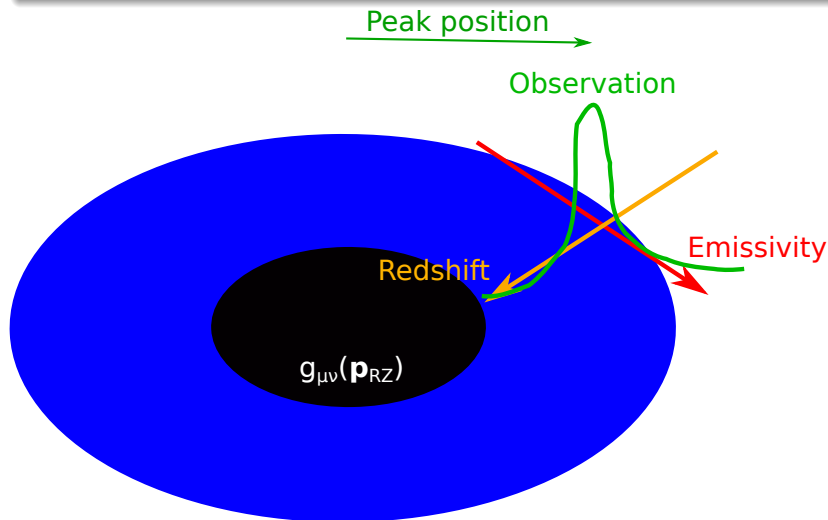

## Cardenas-Avendano+23, PRD, 108, 064043

- $n = 1$  photon ring already follows a circlipse shape

## Carballo-Rubio+24, JCAP, 05, 103

- On photon ring detection prospect

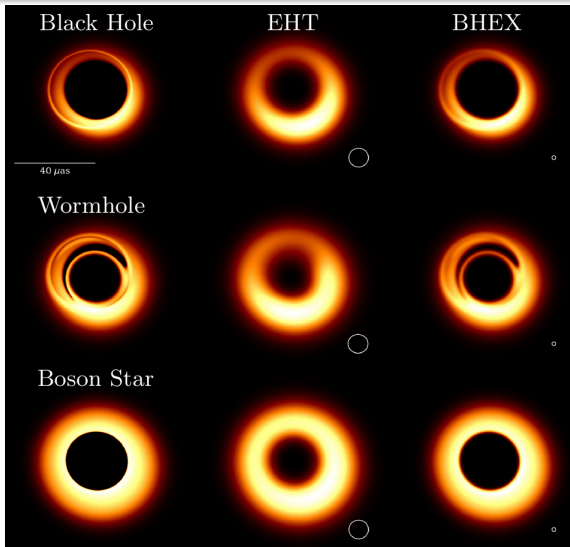

## Urso+24 in prep: Preliminary results

## Urso+24 in prep: Preliminary results

- $n = 0$  image **completely degenerate**
- Total degeneracy for the width of the  $n = 1$  photon ring
- **Geometry and astrophysics disentangleable** with the  $n = 1$  peak

Future? **BH Explorer** (NASA proposed space-VLBI mission)

So much about photon rings!

What about BH shadows??

- 1 Horizon-scale black hole observations
- 2 Photon rings and shadows**
  - Photon rings
  - Shadows**
- 3 Flares and stars
  - Flares
  - Stars

Classical shadow = inside of critical curve

Inner shadow = image of equatorial horizon

“Special-relativistic shadow”

## Black hole shadow

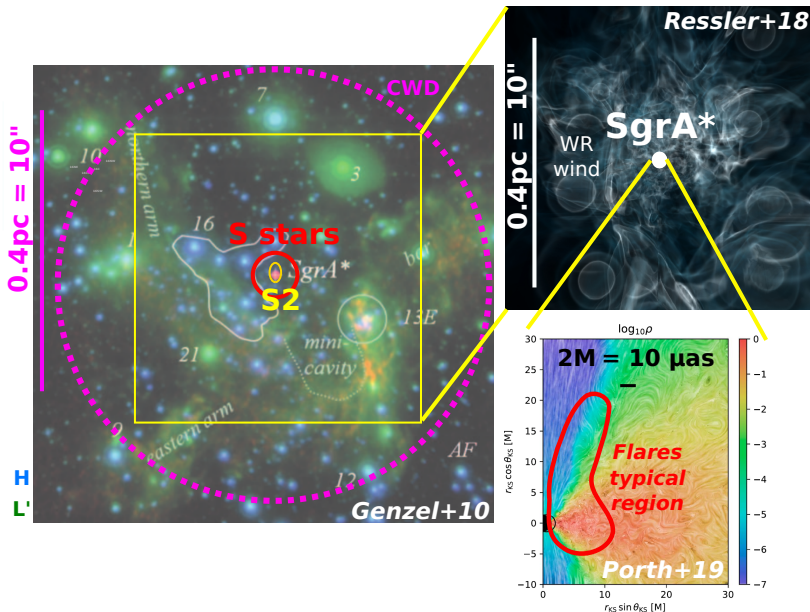

- Very astrophysics-dependent
- Can be dominated by special-relativistic effects
- No “universal feature” as for the photon ring
- Obviously interesting feature, but likely less promising than photon ring for theory testing

- 1 Horizon-scale black hole observations
- 2 Photon rings and shadows
  - Photon rings
  - Shadows
- 3 Flares and stars
  - Flares
  - Stars

  - Shadows
- 3 **Flares and stars**
  - **Flares**
  - Stars

## Observations

- Flare = **transient peaks** of flux on daily basis (4/day in IR)

## Observations

- IR light curve **pseudo period** (at least some events)  
(So likely very close to BH!)

## Modeling: hotspot

- Transient, compact, magnetized parcels of energized plasma, orbiting/ejected close to BH
- Emitting (polarized) non-thermal synchrotron radiation

## Non-polarized

$$I = E^2$$

## Polarized

$$I = E^2 + EVPA$$

$(I, EVPA) \leftrightarrow \text{Stokes } (Q, U)$

- Details on polarized radiation in curved spacetime:  
Aimar+24 [arxiv:2311.18802](https://arxiv.org/abs/2311.18802)

Sky trajectory

Polarization loop

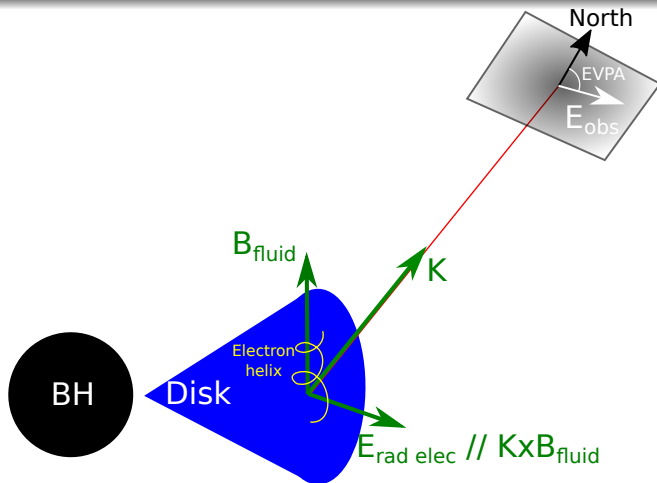

GRAVITY Coll. 2018,23

ALMA/Wielgus+22

## Observed polarized flares

- Astrometry: close to BH ( $r \lesssim 10M$ )
- Polarization loops: vertical B-field

## Why do we care about EVPA?

- Constraint on B field geometry
- Any use for testing the geometry?

## Polarization loops and curvature probing

- Flat-spacetime: **mirror symmetry**
- Curved spacetime: **asymmetric loop** (from light bending)
- *Quantifying curvature?*
- → Vincent, Wielgus, Aimar, Paumard, Perrin A&A 2024

Remember! Plasma physics unknown

- Hopefully, averaging out astro complexity?

## Rosa+22, PRD, 106, 044031

- Hotspots around horizonless objects

GRAVITY Collab. (2023)

## Post-Newtonian orbit integration

$$\ddot{\mathbf{r}} = -\frac{Gm}{r^2} \mathbf{n}_{\text{orb}} + \mathbf{a}_{\text{PN}}$$

$$\mathbf{a}_{\text{PN}} \approx \mathbf{a}_{2\text{PN}} = \mathbf{a}_{\text{Sch}} + \mathbf{a}_{\chi} + \mathbf{a}_{\mathcal{Q}}$$

**Spin? Quadrupole moment??**

**More news soon: Abd El Dayem+24 in prep.**

## Conclusion

- GRAVITY+EHT allow to understand astro close to BH
- Next step: Probing gravity??

## Probing gravity?

- **Photon rings**: great probe but degeneracy with astro; Space-VLBI needed!
- **Flares**: still a lot of astro unknowns.  
Maybe averaging many events can help.  
More data needed!
- **Stellar orbits**: not discussed but promising if closer-in stars discovered! (GRAVITY+)

## Diameter of BH shadow

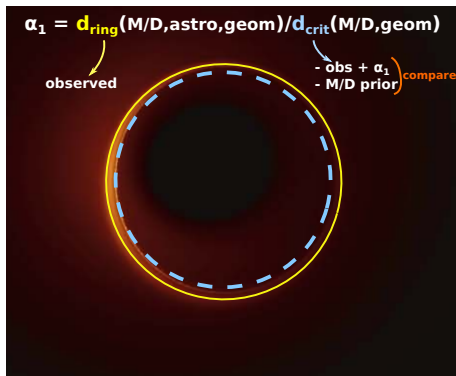

- Scale emission ring to “shadow” (actually, critical curve)  
Compare to critical curve given  $M/D$  prior  
Advocate Kerr consistency test
- Can we trust the GRMHD prediction?

$$\alpha_1 = d_{\text{ring}}(M/D, \text{astro}, \text{geom}) / d_{\text{crit}}(M/D, \text{geom})$$
