

Higgs boson property measurements (mass, width, CP) - CMS

Amrutha Krishna (Northeastern University, Boston, USA),
on behalf of the CMS collaboration

15 July 2025
Higgs Hunting 2025

Introduction

Introduction

Introduction

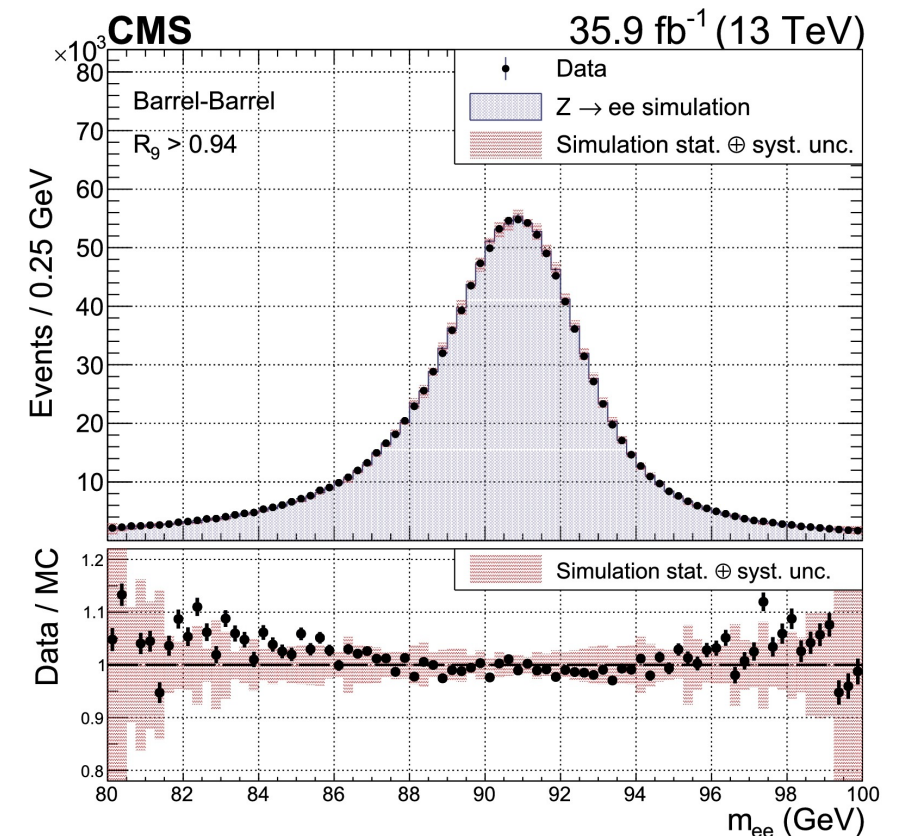

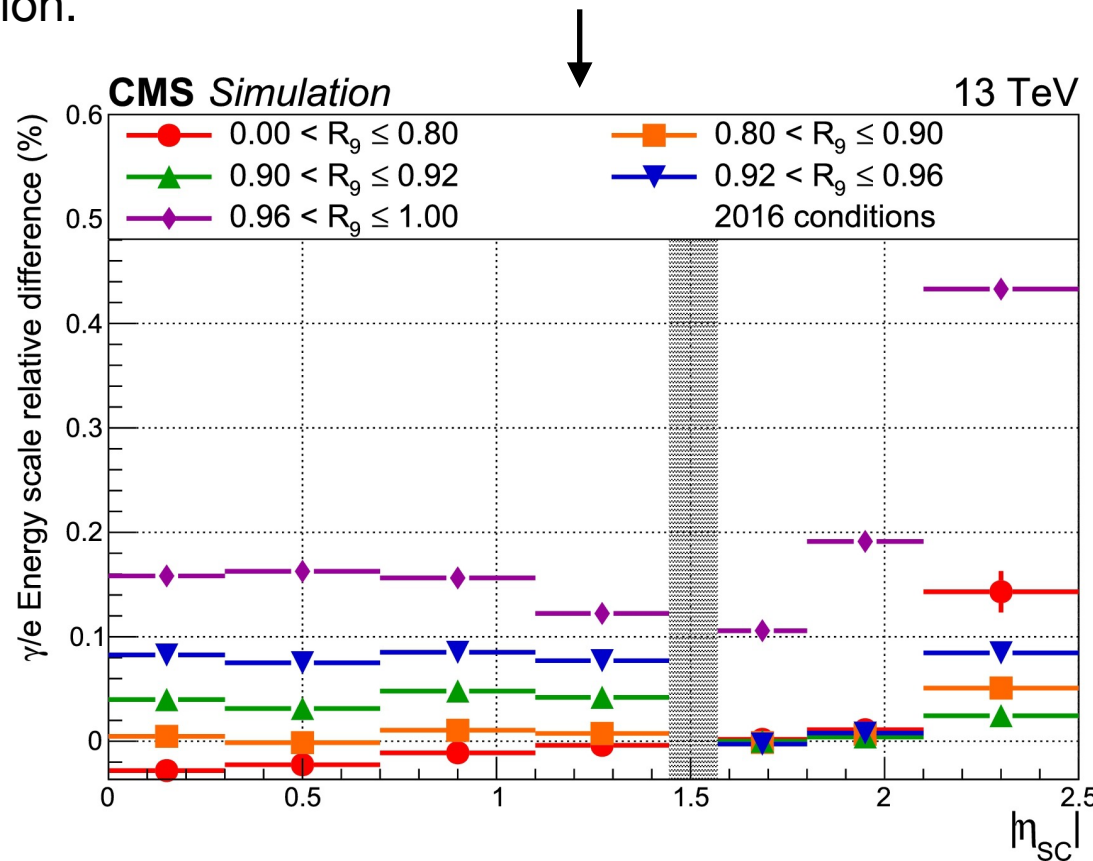

- Precision measurement of m_H :
 - Only **free parameter** in the Higgs sector of the SM; all other Higgs properties depend on it.
 - Precise measurement of m_H using the high resolution decay channels: $H \rightarrow ZZ^* \rightarrow 4l$ and $H \rightarrow \gamma\gamma$.
- Precision measurement of Γ_H :
 - Predicted to be ~ 4.07 MeV for $m_H = 125$ GeV; any deviation points to invisible, BSM decays.
 - Direct measurement from the resonance limited by the detector resolution (~ 1 GeV), **indirect measurement strategies** used for better precision.
- Measurement of CP properties :
 - SM Higgs is CP-even; Probing **CP-violating, anomalous couplings** (ACs) in several Higgs production and decay channels.
 - Important to explain matter/anti-matter asymmetry in universe.

m_H measurement in $H \rightarrow \gamma\gamma$ channel

- Run 2 analysis using 36 fb⁻¹ (2016) data: [Phys. Lett. B, 805 \(2020\)](#)
- Improved precision compared to previous analyses due to refinements in E_γ calibrations and better understanding of systematics:
 - Three-step residual scale and resolution corrections** to E_γ using $Z \rightarrow ee$ events with electrons reconstructed as photons.
 - Scale (resolution) corrections in bins of η , R_9 , p_T (η , R_9) with dedicated systematic uncertainties, including a residual uncertainty for any non-closure of corrections.
 - A method to estimate **systematic uncertainty** on E_γ scale **from non-uniformity in light collection** due to radiation damage along ECAL crystal depth using optical simulation.

m_H measurement in $H \rightarrow \gamma\gamma$ channel

- Analysis performed using ggH and VBF production modes, VH and ttH are not considered as they add complexity to the analysis with negligible improvement in precision.
- 4 ggH + 3 VBF categories defined using a BDT that discriminates signal from background.
- Result:

$$m_H = 125.78 \pm 0.18 \text{ (stat.)} \pm 0.18 \text{ (syst.) GeV}$$

CMS

m_H measurement in $H \rightarrow \gamma\gamma$ channel

- Analysis performed using ggH and VBF production modes, VH and ttH are not considered as they add complexity to the analysis with negligible improvement in precision.
- 4 ggH + 3 VBF categories defined using a BDT that discriminates signal from background.
- Result:

$$m_H = 125.78 \pm 0.18 \text{ (stat.)} \pm 0.18 \text{ (syst.) GeV}$$

CMS

Run 1: 5.1 fb⁻¹ (7 TeV) + 19.7 fb⁻¹ (8 TeV)
2016: 35.9 fb⁻¹ (13 TeV)

— Total □ Stat. Only

Total (Stat. Only)

Run 1 $H \rightarrow \gamma\gamma$		$124.70 \pm 0.34 \text{ (} \pm 0.31 \text{) GeV}$
Run 1 $H \rightarrow ZZ \rightarrow 4l$		$125.59 \pm 0.46 \text{ (} \pm 0.42 \text{) GeV}$
Run 1 Combined		$125.07 \pm 0.28 \text{ (} \pm 0.26 \text{) GeV}$
<hr/>		
2016 $H \rightarrow \gamma\gamma$		$125.78 \pm 0.26 \text{ (} \pm 0.18 \text{) GeV}$
2016 $H \rightarrow ZZ \rightarrow 4l$		$125.26 \pm 0.21 \text{ (} \pm 0.19 \text{) GeV}$
2016 Combined		$125.46 \pm 0.16 \text{ (} \pm 0.13 \text{) GeV}$
Run 1 + 2016		$125.38 \pm 0.14 \text{ (} \pm 0.11 \text{) GeV}$

m_H (GeV)

m_H measurement in $H \rightarrow \gamma\gamma$ channel

- Analysis performed using ggH and VBF production modes, VH and ttH are not considered as they add complexity to the analysis with negligible improvement in precision.
- 4 ggH + 3 VBF categories defined using a BDT that discriminates signal from background.
- Result:

$$m_H = 125.78 \pm 0.18 \text{ (stat.)} \pm 0.18 \text{ (syst.) GeV}$$

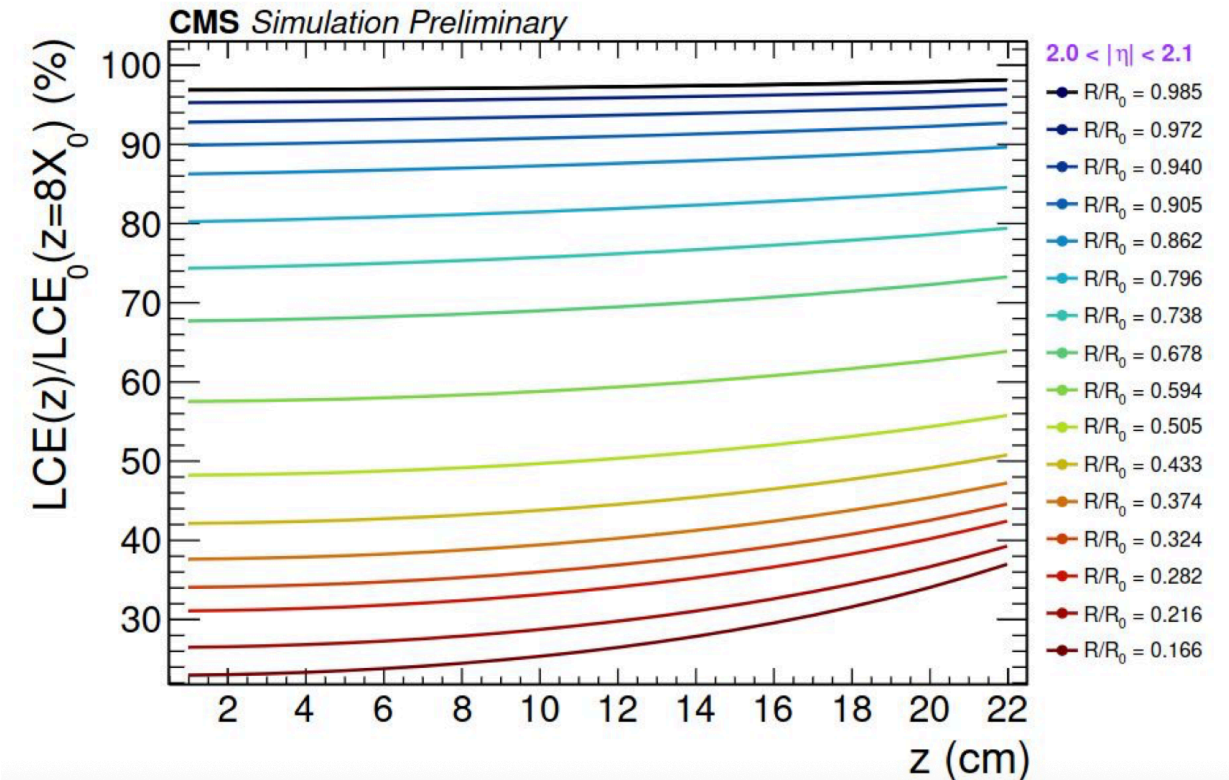

Source	Contribution (GeV)
Electron energy scale and resolution corrections	0.10
Residual p_T dependence of the photon energy scale	0.11
Modelling of the material budget	0.03
Nonuniformity of the light collection	0.11
Total systematic uncertainty	0.18

Towards full Run-2 $H \rightarrow \gamma\gamma$ m_H measurement

- Strategy to mitigate the syst. unc. from **non-uniformity of light collection** in ECAL:
 - Shower maximum of photons deeper than electrons of the same E by $0.85X_0$ in PbWO_4 .
 - Bias in photon energy scale due to **non-uniform radiation damage** along crystal depth and applying $Z \rightarrow ee$ derived calibrations to photons.
 - **Correct photon energy scale** in data using a dedicated light collection efficiency (LCE) model ([CMS-DP-24-045](#)).

$$F = \frac{S^e}{S^\gamma} = \frac{\frac{\int E_{\text{dep}}^e(z) \times \text{LCE}(z; R/R_0, \eta) dz}{\int E_{\text{dep}}^e(z) dz}}{\frac{\int E_{\text{dep}}^\gamma(z) \times \text{LCE}(z; R/R_0, \eta) dz}{\int E_{\text{dep}}^\gamma(z) dz}}$$

Collected energy for damaged crystal

Collected energy for undamaged crystal

- $S^e(S^\gamma)$ = ECAL response to electrons (photons)
- $E_{\text{dep}}(z)$ = shower profile as a function of crystal depth (z) in non-irradiated PbWO_4 simulated using Geant4
- R/R_0 = ECAL crystal transparency measured per-run with a laser-based monitoring system

- Uncertainty in F evaluated from discrepancies between the LCE model and light output measurements on irradiated PbWO_4 in lab tests.
 - 20% in barrel and 35% in endcaps
- Significant reduction in the impact of this systematic uncertainty expected in full Run 2 mass measurement.

m_H and Γ_H measurements in $H \rightarrow ZZ^* \rightarrow 4l$

- **Full Run 2** analysis corresponding to 138 fb⁻¹ of data ([PRD 111 \(2025\) 092014](#)).
- High precision through refinement of calibrations and analysis strategy:
 - $4l$ (4μ , $4e$, $2e2\mu$, $2\mu2e$) tracks constrained to a common vertex compatible with beam spot: 3-8% improvement in mass resolution depending on lepton flavor.
 - On-shell mass constraint applied to one Z boson.
 - Event categorization based on relative mass uncertainty of the four-lepton system ($\delta m_{4l}/m_{4l}$): 10% improvement in Higgs mass resolution.

More details on the analysis methodology in Neha's [talk](#)!

m_H and Γ_H measurements in $H \rightarrow ZZ^* \rightarrow 4l$

- Maximum likelihood fit to m_{4l} and a background-reducing kinematic discriminant D_{bkg}^{kin} .
- Most precise single channel measurement:

$$m_H = 125.04 \pm 0.11 \text{ (stat.)} \pm 0.05 \text{ (syst.) GeV} \rightarrow \text{Stat. limited}$$

CMS

m_H and Γ_H measurements in $H \rightarrow ZZ^* \rightarrow 4l$

- Maximum likelihood fit to m_{4l} and a background-reducing kinematic discriminant D_{bkg}^{kin} .
- Most precise single channel measurement:

$$m_H = 125.04 \pm 0.11 \text{ (stat.)} \pm 0.05 \text{ (syst.) GeV} \rightarrow \text{Stat. limited}$$

- Direct Γ_H from fitting the invariant mass distribution of $4l$ with a Breit-Wigner (BW) convoluted with a double sided Crystal Ball (DCB) function.
- Result:

$$\Gamma_H < 50 \text{ (330) MeV at 68% (95%) C.L.}$$

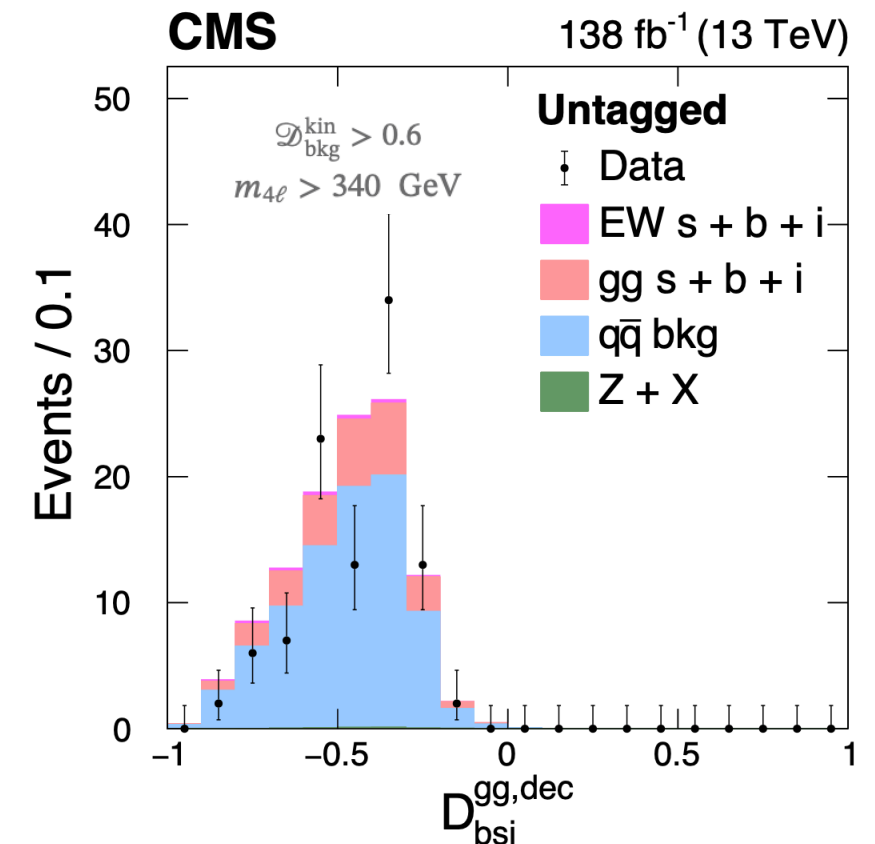

Off-shell Γ_H measurements in $H \rightarrow ZZ \rightarrow 4l$

- Utilizes the different dependence of on-shell and off-shell cross-sections on the width.

$$\frac{\sigma_{gg \rightarrow H \rightarrow ZZ^*}^{on-shell}}{\sigma_{gg \rightarrow H^* \rightarrow ZZ}^{off-shell}} \propto \frac{g_g^2 g_Z^2 / m_H \Gamma_H}{g_g^2 g_Z^2 / 4m_Z^2} \propto \Gamma_H$$

- Assumes identical on-shell/off-shell couplings**, i.e., no new physics alters the coupling in off-shell case.
- Significant destructive interference between H signal and non-resonant $4l$ production in the off-shell region.
- Interference and cross contamination from on-shell H taken into account in the PDF describing data.
- Events separated based on production mode: VBF, VH & ggH.
- Two **kinematic discriminants** built to tag interference (D_{int}) and background events (D_{bkg}).
- Likelihood fit performed using observables: m_{4l} , D_{int} , D_{bkg} .

Off-shell Γ_H measurements in $H \rightarrow ZZ \rightarrow 4l$

- Measurement compatible with SM:

$$\Gamma_H = 2.9^{+2.3}_{-1.7} \text{ MeV}$$

- Combination with off-shell $2l2\nu$ channel ([Nature Physics 18, 1329-1334, 2022](#)):

$$\Gamma_H = 3.0^{+2.0}_{-1.5} \text{ MeV}$$

- SM dependency studied** by introducing a heavy quark Q in the ggH loop.
 - An unconstrained coupling strength κ_Q included in the PDF parametrization using EFT-based MC templates.
 - Value of κ_Q constrained by on-shell/off-shell data and bounds on Γ_H is less stringent but consistent with $\kappa_Q = 0$.
 - Stricter constraints on κ_Q possible with future combinations with other on-shell measurements.
- $\mu_{\text{off-shell}} = 0$ **excluded** with a CL corresponding to 3.8σ

AC measurements in $H \rightarrow \gamma\gamma$

- **New full Run-2** analysis ([CMS-PAS-HIG-24-006](#)).
- **HVV** ACs through $H \rightarrow \gamma\gamma$ events produced via VBF and VH modes, and **Hgg** AC through ggH + 2 jets events.
- As per usual practice, AC measurements expressed in terms of **cross-section fractions** (systematic uncertainties cancel out):

$$f_{ai} = \frac{|a_i|^2 \sigma_i}{\sum_j |a_j|^2 \sigma_j} \text{sign}(a_i/a_1)$$

- Analysis categories defined and optimized using **MELA** paired with **ML** discriminants to maximize the sensitivity to a CP-odd signal.
- Four HVV and one Hgg AC cross-section ratios measured using a simultaneous maximum likelihood fit to the $m_{\gamma\gamma}$ spectra across all categories.
- Results **consistent with SM** as well as with previous measurements.

$$A(HVV) \sim \left[a_1^{VV} + \frac{k_1^{VV} q_{V1}^2 + k_2^{VV} q_{V2}^2}{(\Lambda_1^{VV})^2} \right] m_{V1}^2 \epsilon_{V1}^* \epsilon_{V2}^* + a_2^{VV} f_{\mu\nu}^{*(1)} f^{*\mu\nu(2)} + a_3^{VV} f_{\mu\nu}^{*(1)} \tilde{f}^{*\mu\nu(2)}$$

SM : VV = ZZ, WW
CP Even (higher order couplings)
CP Even
CP Odd

($\Lambda_1 = 1\text{TeV}$)

Parameter	Expected / (10^{-4}) 95% CL $H \rightarrow \gamma\gamma$	Observed / (10^{-4}) 95% CL $H \rightarrow \gamma\gamma$
f_{a3}	$[-5.4, 5.4]$	$[-1.5, 1.5]$
f_{a2}	$[-8.8, 10]$	$[-5.5, 1.2]$
$f_{\Lambda 1}$	$[-0.48, 1.2]$	$[-0.36, 0.17]$
$f_{\Lambda 1}^{Z\gamma}$	$[-9.5, 9.9]$	$[-2.5, 4.8]$

Some of the most stringent limits to date!

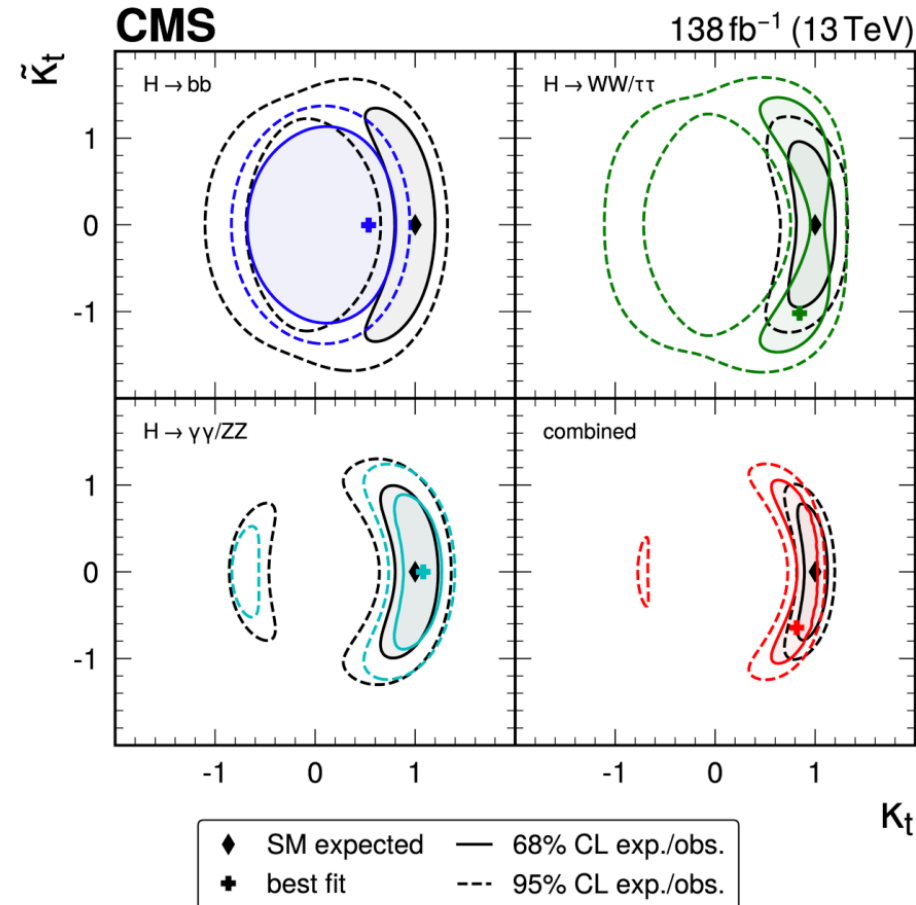

See Federica's [talk](#) for more details!

Other AC searches

- Search for anomalous HVV and Hgg couplings using $H \rightarrow WW$ production (VBF, VH, ggH + 2 jets) and decay (different-flavor dilepton final states) ([EPJC 84, 779 \(2024\)](#)).
- MELA-based kinematic discriminants to increase the sensitivity at the production vertex.
- AC measurements in terms of cross-section fractions.
- Additionally, a simultaneous measurement of four HVV ACs \longrightarrow performed in the SMEFT framework.
- All results are consistent with the SM.

- AC search using ttH(bb) and tH production ([JHEP 02 \(2025\) 097](#)).
- top-Higgs coupling parametrized with purely CP-even (κ_t) and CP-odd ($\tilde{\kappa}_t$) terms.
- Best-fit values after combination with other H decay channels: $(\kappa_t, \tilde{\kappa}_t) = (0.82, -0.65)$

Summary

- Presented results of Higgs boson mass and natural width measurements in CMS using $H \rightarrow ZZ \rightarrow 4l$ and $H \rightarrow \gamma\gamma$ channels.
- Most precise single channel m_H measurement using full Run2 $H \rightarrow ZZ \rightarrow 4l$ data:
$$m_H = 125.04 \pm 0.11 \text{ (stat.)} \pm 0.05 \text{ (syst.) GeV}$$
- Best constraints on Γ_H from indirect off-shell/on-shell cross-section ratio measurement in $H \rightarrow ZZ \rightarrow 4l$ channel:
$$\Gamma_H = 3.0^{+2.0}_{-1.5} \text{ MeV}$$
- Presented studies towards reducing systematic uncertainty due to non-uniformity of light collection in full Run2 $H \rightarrow \gamma\gamma$ mass measurement.
- Results of CP-violating, anomalous couplings searches presented in several Higgs production and decay channels — consistent with SM expectation of purely CP-even interactions.

Backup

m_H measurement in $H \rightarrow \gamma\gamma$ channel

- **Multi-step residual scale and resolution corrections** to E_γ (following ECAL calibration and multivariate regression), using $Z \rightarrow ee$ events with electrons reconstructed as photons.
 - Per LHC-fill corrections to account for shift in E_γ scale due to ECAL radiation damage.
 - Scale & resolution corrections derived simultaneously in fine bins of R_9 (shower shape variable to distinguish converted/unconverted photons) and η .
 - Final scale corrections derived in bins of η and p_T to address residual non-linearity in ECAL response and differences in e/γ energy spectra between $Z \rightarrow ee$ and $H \rightarrow \gamma\gamma$ decays.
- Systematic uncertainty on E_γ scale and resolution corrections evaluated by varying R_9 and $Z \rightarrow ee$ event selections.
- Scale corrections re-applied to data and their deviation from unity applied as a residual uncertainty due to non-closure of corrections.
- Estimated **systematic uncertainty** on E_γ scale **from non-uniformity in light collection** due to radiation damage along ECAL crystal depth
 - derived from optical simulation and validated with test beam data on irradiated crystals.

m_H measurement in $H \rightarrow \gamma\gamma$ channel

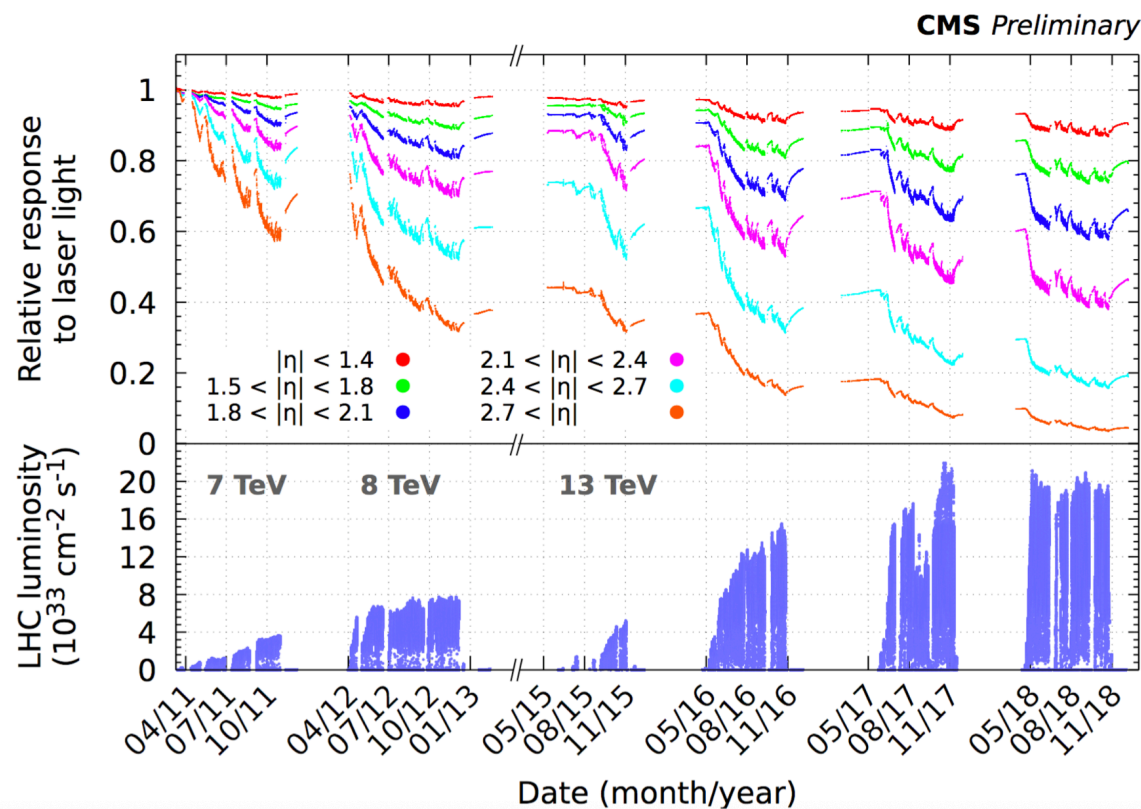

- Parametric signal model per production mode, category and right/wrong vertex scenario from MC — $m_{\gamma\gamma}$ distributions fitted with a sum of upto 4 Gaussians.
- Background models from fits to data side-bands — discrete profiling of plausible PDFs in the final likelihood fit.

FNUF corrections

- Shower maximum of photons deeper than electrons of the same E by $0.85X_0$ in PbWO_4 .
- Bias in photon energy scale due to **non-uniform radiation damage** along crystal depth and applying $Z \rightarrow ee$ derived calibrations to photons.
- Light collection efficiency (LCE) as a function of crystal depth (z), transparency loss (R/R_0) and η simulated using Fluka + Litrani.

- **MELA discriminants paired with ML algorithms** for maximum sensitivity. For eg., VBF events divided into two bins in each of the following three discriminants:
 - D_{0-}^{VBF} (MELA-based, CP-even/CP-odd separation),
 - $D_{NNBSM}^{VBF}, D_{NNbkg}^{VBF}$ (DNN-based, VBF sig/bkg separation, SM VBF/BSM separation)
- Categories optimized by scanning each discriminant to maximize the sensitivity to a CP-odd signal.

$$a_1^{WW} = a_1^{ZZ},$$

$$\delta c_z = \frac{1}{2} a_1^{ZZ} - 1,$$

$$a_2^{WW} = c_w^2 a_2^{ZZ},$$

$$c_{zz} = -\frac{2s_w^2 c_w^2}{e^2} a_2^{ZZ},$$

$$a_3^{WW} = c_w^2 a_3^{ZZ},$$

$$\tilde{c}_{zz} = -\frac{2s_w^2 c_w^2}{e^2} a_3^{ZZ},$$

$$\frac{\kappa_1^{WW}}{(\Lambda_1^{WW})^2} = \frac{1}{c_w^2 - s_w^2} \left(\frac{\kappa_1^{ZZ}}{(\Lambda_1^{ZZ})^2} - 2s_w^2 \frac{a_2^{ZZ}}{m_Z^2} \right),$$

$$c_{z\Box} = \frac{m_Z^2 s_w^2}{e^2} \frac{\kappa_1^{ZZ}}{(\Lambda_1^{ZZ})^2},$$

$$\frac{\kappa_2^{Z\gamma}}{(\Lambda_1^{Z\gamma})^2} = \frac{2s_w c_w}{c_w^2 - s_w^2} \left(\frac{\kappa_1^{ZZ}}{(\Lambda_1^{ZZ})^2} - \frac{a_2^{ZZ}}{m_Z^2} \right),$$
