**NUCLÉAIRE
& PARTICULES**

Introduction

Neutrino Oscillation in a Micro-Nutshell

■ Neutrinos can be observed as **mass** ($i=1,2,3$) or **flavor** ($\alpha=e,\mu,\tau$) eigenstates

$$\underline{|\nu_\alpha\rangle} = \sum_{i=1}^3 U_{\alpha i} \underline{|\nu_i\rangle}$$

+ This Neutrino Flavor Mixing makes neutrino **oscillations** possible :
A neutrino created in given flavor state can be measured later in a different flavor, even in the absence of interaction.

■ Neutrino mixing described via the *Pontecorvo-Maki-Nakagawa-Sakata* (PMNS) matrix.

$$\begin{bmatrix} U_{e1} & U_{e2} & U_{e3} \\ U_{\mu 1} & U_{\mu 2} & U_{\mu 3} \\ U_{\tau 1} & U_{\tau 2} & U_{\tau 3} \end{bmatrix} = \begin{bmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta_{CP}} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta_{CP}} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta_{CP}} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta_{CP}} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta_{CP}} & c_{23}c_{13} \end{bmatrix} \quad \begin{matrix} C_{ij} = \cos \theta_{ij} \\ S_{ij} = \sin \theta_{ij} \end{matrix}$$

(Parameterisation assuming unitarity)

■ The oscillation probability

$$P(\nu_\alpha \rightarrow \nu_\beta) = \sum_{j,k} U_{\alpha,j}^* U_{\alpha,k} U_{\beta,j} U_{\beta,k}^* \times \exp\left(-i \frac{L}{2E} \Delta m_{kj}^2\right)$$

$$\theta_{12}, \theta_{23}, \theta_{13}, \delta_{CP}$$

$$\Delta m_{kj}^2 = m_k^2 - m_j^2$$

In practice : $\Delta m_{21}^2, \Delta m_{31}^2$

Oscillation can take many forms, depending on :

- + The neutrino E
- + The distance from production L ($\sim$ time)
- + The channel
 - $\alpha \rightarrow \alpha$ (survival/disappearance)
 - $\alpha \rightarrow X$ (oscillation/appearance)

Neutrino Oscillation in a Micro-Nutshell

- Many kinds of neutrino experiments in the past decades...
- Among the main ones now or soon, experiments observing neutrinos in $\sim \text{GeV}$ regime:
 - + *Survival of ν_μ*
 - + *Appearance of ν_e in a ν_μ beam.*
 - + *Produced by an accelerator or in the atmosphere.*
 - + *Measured hundreds of kms later.*
 - + *Compare the oscillations of neutrinos vs. antineutrinos.*

Neutrino Oscillation in a Micro-Nutshell

■ Many kinds of neutrino experiments in the past decades...

■ Among the main ones now or soon, experiments observing neutrinos in $\sim \text{GeV}$ regime:

- + *Survival of ν_μ*
- + *Appearance of ν_e in a ν_μ beam.*
- + *Produced by an accelerator or in the atmosphere.*

Open questions in neutrino physics

Neutrino Mass Ordering (NMO)

Linked

- ✓ CP-violating phase
- ✓ Octant of θ_{23} mixing angle
- ✓ Absolute mass-scale
- ✓ Origin of neutrino mass
- ✓ $0\nu\beta\beta$ & (Dirac vs Majorana)
- ✓ Existence of sterile neutrino
- ✓ Non-Standard Interactions in lepton sector

■ These experiments measure the NMO thanks to the interaction of neutrinos with matter, and are sensitive at the same time to the NMO, to δ_{CP} , to θ_{23} ...

=> Interest for an experiment which can measure the NMO without having to disentangle all this, and undergoing no matter effect (where New Physics could appear !).

Motivations of the JUNO Experiment

■ Neutrino Mass Ordering (NMO)

+ *To better understand the mechanisms at play to generate flavor & mass.*

■ Precision measur't of Flavor Mixing in lepton sector

$$\Delta m_{31}^2, \Delta m_{21}^2, \sin^2 \theta_{12}$$

+ *Challenge the 3- ν model to explore beyond the SM (unitarity, non-standard int., ...)*

■ Rich physics possibilities

+ *Beyond reactor neutrinos: solar neutrinos, atmospheric neutrinos.*

+ *Beyond neutrino physics: neutrinos as probes for astrophysics (SN) or geology (geo- ν 's)*

Measuring the NMO

$$\mathcal{P}(\bar{\nu}_e \rightarrow \bar{\nu}_e) = 1 - \sin^2 2\theta_{12} c_{13}^4 \sin^2 \Delta_{21} - \frac{1}{2} \sin^2 2\theta_{13} (\sin^2 \Delta_{31} + \sin^2 \Delta_{32}) - \frac{1}{2} \cos 2\theta_{12} \sin^2 2\theta_{13} \sin \Delta_{21} \sin(\Delta_{31} + \Delta_{32})$$

■ Measure the interference between solar and atmospheric oscillations.

+ Makes the $\bar{\nu}_e$ disappearance probability depend on the sign of $\Delta_{31} \propto \Delta m_{31}^2$

+ NMO measurement depends on nothing else.

■ JUNO must be able to measure **very precisely** the E spectrum to tell **NO** from **IO**

■ Ingredients:

+ Presence of this peculiar oscillation pattern

+ High statistics

+ A favorable detection channel.

+ Minimal backgrounds

+ Very precise and well understood E reconstruction

Measuring the NMO

Ingredients:

- + Presence of this peculiar oscillation pattern
 - > detector ~50km from a $O(1)$ MeV neutrino source.

- + High statistics
 - > Many reactors + Large detector.

- + A favorable detection channel (IBD).

- + Minimal backgrounds
 - > Deep underground detector,
segmented for vetoes.

- + Very precise and well understood E reconstruction
 - > Optimized liquid scintillator
 - > Sophisticated reconstruction
 - > Instrumental redundancy.

Design overview

■ Optimized LS in the Central Detector (CD)

■ Muon veto

■ Redundant PMT systems

+ 17612 20-inch PMTs (LPMTs)

+ 25600 3-inch PMTs (SPMTs)

The Jiangmen Underground Neutrino Observatory

*Underground lab (700 m),
located in China.*

*A 35 m diameter sphere: 20kton of LS
Surrounded by a Cerenkov detector*

Site and detector built from 2015 to Dec. 2024

Physics operations started in Aug. 2025.

Engines on !

- After years of design & construction, JUNO's now taking data (physics: since Aug. 25)
- Sensitivity studies suggested world leading solar parameters with early data.

From *Chin.Phys.C* 46 (2022) 12, 123001, [arXiv:2204.13249](#)

	Central Value	PDG2020	100 days
$\Delta m_{31}^2 (\times 10^{-3} \text{ eV}^2)$	2.5283	± 0.034 (1.3%)	± 0.021 (0.8%)
$\Delta m_{21}^2 (\times 10^{-5} \text{ eV}^2)$	7.53	± 0.18 (2.4%)	± 0.074 (1.0%)
$\sin^2 \theta_{12}$	0.307	± 0.013 (4.2%)	± 0.0058 (1.9%)
$\sin^2 \theta_{13}$	0.0218	± 0.0007 (3.2%)	± 0.010 (47.9%)

How up to this first challenge we've been is presented today.

Engines on !

- After years of design & construction, JUNO's now taking data (physics: since Aug. 25)
 - Sensitivity studies suggested world leading solar parameters with early data.
 - Above all, the first years of operations are a learning phase, to design methods to...
 - + *Characterise and calibrate detector effects.*
 - + *Reconstruct events*
 - + *Identify & reject backgrounds, determine the shape and rates of what remains.*
 - + *Interpret statistically the IBD e^+ energy spectrum to extract oscillation physics, via a model that incorporates :*
 - > *Initial antineutrino spectrum, inclusion of reactor information*
 - > *Energy model (resolution and non linearity)*
 - > *Systematic uncertainties (dozens of nuisance parameter).*
- ...with enough precision and robustness to eventually be able to measure the NMO, and oscillation parameters at the subpercent level.

Reconstruction and Calibration

Energy and position reconstruction

$$\frac{\sigma_{E^{\text{rec}}}}{E^{\text{vis}}} = \sqrt{\left(\frac{a}{\sqrt{E^{\text{vis}}}}\right)^2 + b^2 + \left(\frac{c}{E^{\text{vis}}}\right)^2}$$

- Needed for the NMO : $\sigma E/E = 3\%$ @ 1 MeV & E-scale understood @ $< 1\%$.
- 2 key ingredients (>1600 PE @ 1 MeV + 78% PMT coverage) do not suffice !
=> A sophisticated reconstruction is also essential.
- Main E & vertex reconstruction methods maximize likelihoods. Ex:

$$L(E_{\text{rec}}) = \prod_j^{\text{Unhit LPMTs}} P_j(\text{unhit}|\mu_{j,\text{exp}}) \times \prod_i^{\text{Hit LPMTs}} P_i(Q_{i,\text{obs}}|\mu_{i,\text{exp}})$$

+ Based on the Charge and Hit time PDFs expected in each PMT, as a function of the value and position of the E deposit.

+ Determining these PDFs: a precision work. Relies on : calibration sources, ^{214}Po decays, laser sources, ...

+ Impacted by: spatial & time variation of gains, of LS state, transparency, radiopurity, WF recons., ...

=> Long work with calibration & control samples, progressively reach design perf.

JUNO's calibration

■ 5 γ and 2 neutron sources: characterise a large E span.

■ Confirms the Light Yield (above expectancies)

*^{68}Ge (1.022 MeV)
and AmC (2.2 MeV) data*

JUNO's calibration

■ 5 γ and 2 neutron sources: characterise a large E span.

■ Confirms the Light Yield (above expectancies)

*^{68}Ge (1.022 MeV)
and AmC (2.2 MeV) data*

JUNO's calibration

Non linearity known @ 1 %

Role of the SPMT system

JUNO's calibration

Energy scale uniformity

+ Uniformity better than $\pm 1\%$ within $R < 16.5$ m (FV)
²¹⁴-Po visible $E \sim 0.9$ MeV

Energy resolution

+ 3.4% @ 1 MeV @ detector center
Stochastic term @ 3.3%

IBD sample selection

Selecting the antineutrino sample

Main signal detection principle

The final selection needs more complex criteria to mitigate backgrounds which mimic this coincidence.

Cosmogenics (muon-induced)

^9Li ^8He

Spallation neutrons.

Natural radioactivity

^{214}Bi - ^{214}Po

$^{13}\text{C}(\alpha, n)^{16}\text{O}$

Accidentals

Other neutrinos

Atmospheric neutrinos
IBDs: Geoneutrinos,
World Reactors

■ Muon veto

Removes all events <5 ms after a muon seen in the CD or WP.

Cuts short lived spallation products

■ Spatial & temporal veto around spallation neutrons

Removes all events <4 m from a spallation neutron, for 1.2 s after this neutron.

Cuts long lived spallation products like ${}^9\text{Li}$ ${}^8\text{He}$

■ Finally form pairs of prompt+delayed events

Keep pairs with $\Delta t < 1$ ms and $\Delta d < 1.5$ m

*Multiplicity cut: no additional events in
 $[t_{\text{delayed}} - 2\text{ms}; t_{\text{delayed}} + 1\text{ms}]$*

■ Fiducial Volume: $R < 16.5$ m.

Cuts Accidental & part of muon induced backgrounds.

■ 2379 $\bar{\nu}_e$ candidates in 59.1 days.

37 true IBDs / day

Signal efficiency: ~ 70%

Purity: 86 %

Backgrounds (cpd)

	Pre-fit	Best-fit
$^9\text{Li}/^8\text{He}$	4.3 ± 1.4	3.9 ± 0.6
Geoneutrinos	1.2 ± 0.5	1.4 ± 0.4
World reactors	0.88 ± 0.09	0.88 ± 0.09
$^{214}\text{Bi}-^{214}\text{Po}$	0.18 ± 0.10	0.20 ± 0.10
$^{13}\text{C}(\alpha, n)^{16}\text{O}$	0.04 ± 0.02	0.04 ± 0.02
Fast neutrons	0.02 ± 0.02	0.02 ± 0.02
Double neutrons	0.05 ± 0.05	0.07 ± 0.05
Atmospheric neutrinos	0.08 ± 0.04	0.07 ± 0.04
Accidentals ($\times 10^{-2}$)	4.9 ± 0.3	4.9 ± 0.3

Constructing the Fit Model

1. True non-oscillated spectrum of detected $\bar{\nu}_e$

- Start from Huber-Mueller prediction

- Elementary brick of a combination of

 - + 4 isotopes (^{235}U , ^{238}U , ^{239}Pu , ^{241}Pu)

 - + 4 fission fractions

 - + 4 values of the E released per fission

 - + 1 Reactor Thermal Power

Repeated over 10 reactors

- Add Non-equilibrium & Spent Fuel corr.

- Split in 21 segments to apply additional shape corrections.

 - + Constrained by a simultaneous fit to Daya Bay's near detectors data.

=> ~75 fitted nuisance parameters
(not counting DYB's)

- Multiply by the IBD X-section $\frac{d\sigma}{d\cos\theta}(E_{\bar{\nu}_e}, \cos\theta)$

2. Oscillation

■ Apply the oscillation probability

$$\mathcal{P}(\bar{\nu}_e \rightarrow \bar{\nu}_e) \cong -\sin^2 2\theta_{12} c_{13}^4 \sin^2 \Delta_{21} - \frac{1}{2} \sin^2 2\theta_{13} (\sin^2 \Delta_{31} + \sin^2 \Delta_{32}) - \frac{1}{2} \cos 2\theta_{12} \sin^2 2\theta_{13} \sin \Delta_{21} \sin(\Delta_{31} + \Delta_{32})$$

=> 5 fitted parameters
(oscillation params + Matter density)

3. Detect. effects

■ From $E(\bar{\nu}_e)$ to E_{vis} to E_{rec} + Non linearity model + Resolution model

=> 7 nuisance parameters

Illustration from *Chin.Phys.C* 46 (2022) 12, 123001

4. Backgrounds

■ Rate & Shapes: + Mostly data driven + Complemented with MC ■ Selection eff.

=> >10 nuisance parameters

Results

World best solar oscillation parameters measurement.

$$\sin^2 \theta_{12} = 0.3092 \pm 0.0087,$$

$$\Delta m_{21}^2 = (7.50 \pm 0.12) \times 10^{-5} \text{ eV}^2.$$

Uncertainties

	PDG 2025	JUNO (59.1 days)
Δm_{21}^2	2.5%	1.6%
$\sin^2 \theta_{12}$	3.9%	2.8%

■ $\sigma(\text{stat}) \sim \frac{3}{4}$ of total uncertainty.

■ Main systematic uncertainties:

+ Backgrounds

+ Energy response model

+ Detector efficiency

+ Reactor info

+ More marginal: $\overline{\nu}_e$ spectrum shape

=> Mostly treated via > 100 nuisance parameters

Robustness

■ Essential to precision physics

■ JUNO's bias killing policy based on

+ *Thorough* comparison of 3 distincts analysis groups.

+ *Blinding strategy* that conceals the oscillation parameters and reactor info until the analysis design is frozen.

Looking forward

■ 59.1 days: not enough for a precise Δm^2_{31}

+ Requires a sophisticated statistical treatment
(e.g. à la Feldman-Cousins)

■ A continuous hard work to progress on the path to precision physics (crucial for NMO!)

+ Improved Energy resolution and Energy model

+ TAO data available for future analyses.

+ Improved understanding of backgrounds.

■ Hints at the NMO may arrive earlier thanks to synergies with experiments exploiting Accelerators or Atmospheric neutrinos.

JUNO-only sensitivity in years to come

The Taishan Antineutrino Observatory (TAO)

■ Will constrain the unoscillated $\bar{\nu}_e$ spectrum shape

+ Relies on *very high statistics* and
exceptional energy resolution (design: $\sim 2\%$ @ 1 MeV)

■ 1-ton fiducial volume of Gd-doped LS

+ 40 m from one of Taishan's cores (4.6 GWth)

+ *IBD rate: 30*JUNO*

+ Photon detection yield : *4500 PE/MeV !!*

■ Detection: 10 m² of SiPM

+ Photon detection efficiency : 50%

+ *Photo coverage: 95%*

Started physics data taking in Feb' 26

Looking forward

■ 59.1 days: not enough for a precise Δm_{31}^2

+ Requires a sophisticated statistical treatment
(e.g. à la Feldman-Cousins)

■ A continuous hard work to progress on the path to precision physics (crucial for NMO!)

+ Improved Energy resolution and Energy model

+ TAO data available for future analyses.

+ Improved understanding of backgrounds.

■ Hints at the NMO may arrive earlier thanks to synergies with experiments exploiting Accelerators or Atmospheric neutrinos.

JUNO-only sensitivity in years to come

Looking forward (II): JUNO's wide scientific spectrum

Summary

■ JUNO has successfully started to take data and produce physics results.

■ A successful first campaign showing that the global measurement chain – **detection, reconstruction, calibration, selection, robust statistical procedure** – is already in a good shape

+ Proven by measuring solar parameters better than the World average, as expected.

+ A remarkable achievement for a detector of this scale, after only a few months of commissioning and physics operation.

	PDG 2025	JUNO (59.1 days)
Δm_{21}^2	2.5%	1.6%
$\sin^2 \theta_{12}$	3.9%	2.8%

■ We're now sharpening our tools to be ready for precision physics (Δm_{31}^2 , NMO)

■ Stay tuned !

+ Short term: summer conferences

+ Longer term: JUNO's wide physics program.
