

# TIANLAI DISH ARRAY CONFIGURATION

R. ANSARI - JULY 2014

- Comparison of several configurations for the Tianlai 16-dish array, and survey strategy
- Based on work being done by Jiao Zhang
- Computation of reconstructed beams from visibilities, Transfer function and noise power spectrum
- Assume transit mode operation, with several scans along the declination, and complete beam knowledge
- assume stationary white noise for the visibilities as a function of time  $V_{ij}(t) \rightarrow V_{ij}(\alpha)$

Sky :  $\alpha$  (RA, East – West, EW)

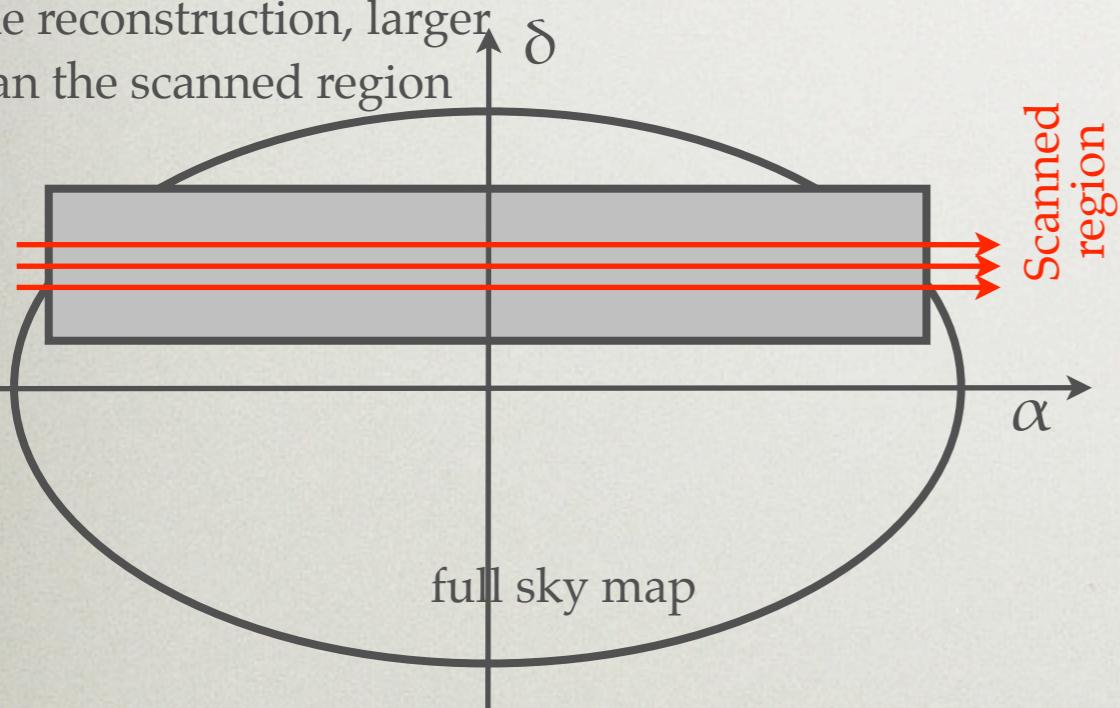

$\delta$  (DEC, North – South, NS)

Fourier :  $(\alpha, \delta) \rightarrow (u, v)$

Sky :  $I(\alpha, \beta) \rightarrow F(u, v)$

Visibilities :  $V_{ij}(\alpha) \rightarrow \tilde{V}_{ij}(u)$

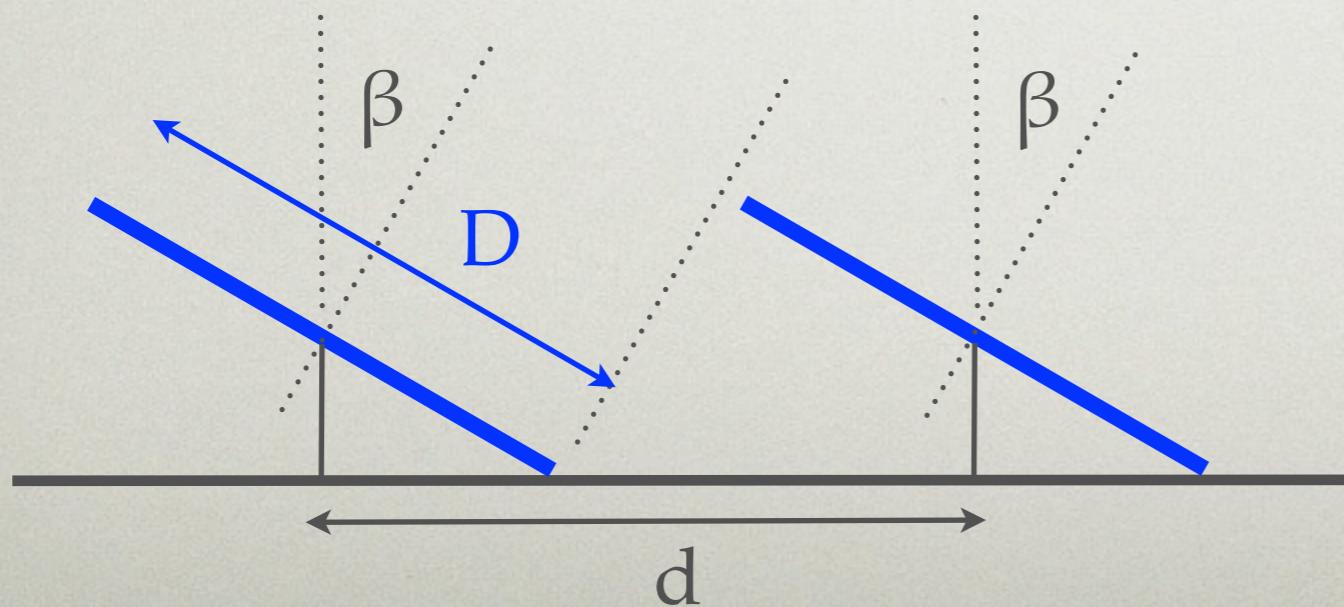

Rectangular geometry used  
in the reconstruction, larger  
than the scanned region

$$\begin{aligned}
 \left( \tilde{V}_{ij}(u) \right) &= [A_u] \times (F_u(v)) + (n) \\
 \left( \hat{F}_u(v) \right) &= [B_u] \times \left( \tilde{V}_{ij}(u) \right) \\
 \left\{ \hat{F}_u(v) \right\} &\rightarrow \hat{F}(u, v) \\
 \hat{F}(u, v) &\rightarrow \hat{F}_W(u, v) = \hat{F}(u, v) \times W(u, v) \\
 \hat{F}_W(u, v) &\rightarrow \hat{I}(\alpha, \delta) \quad (\text{FFT})
 \end{aligned}$$

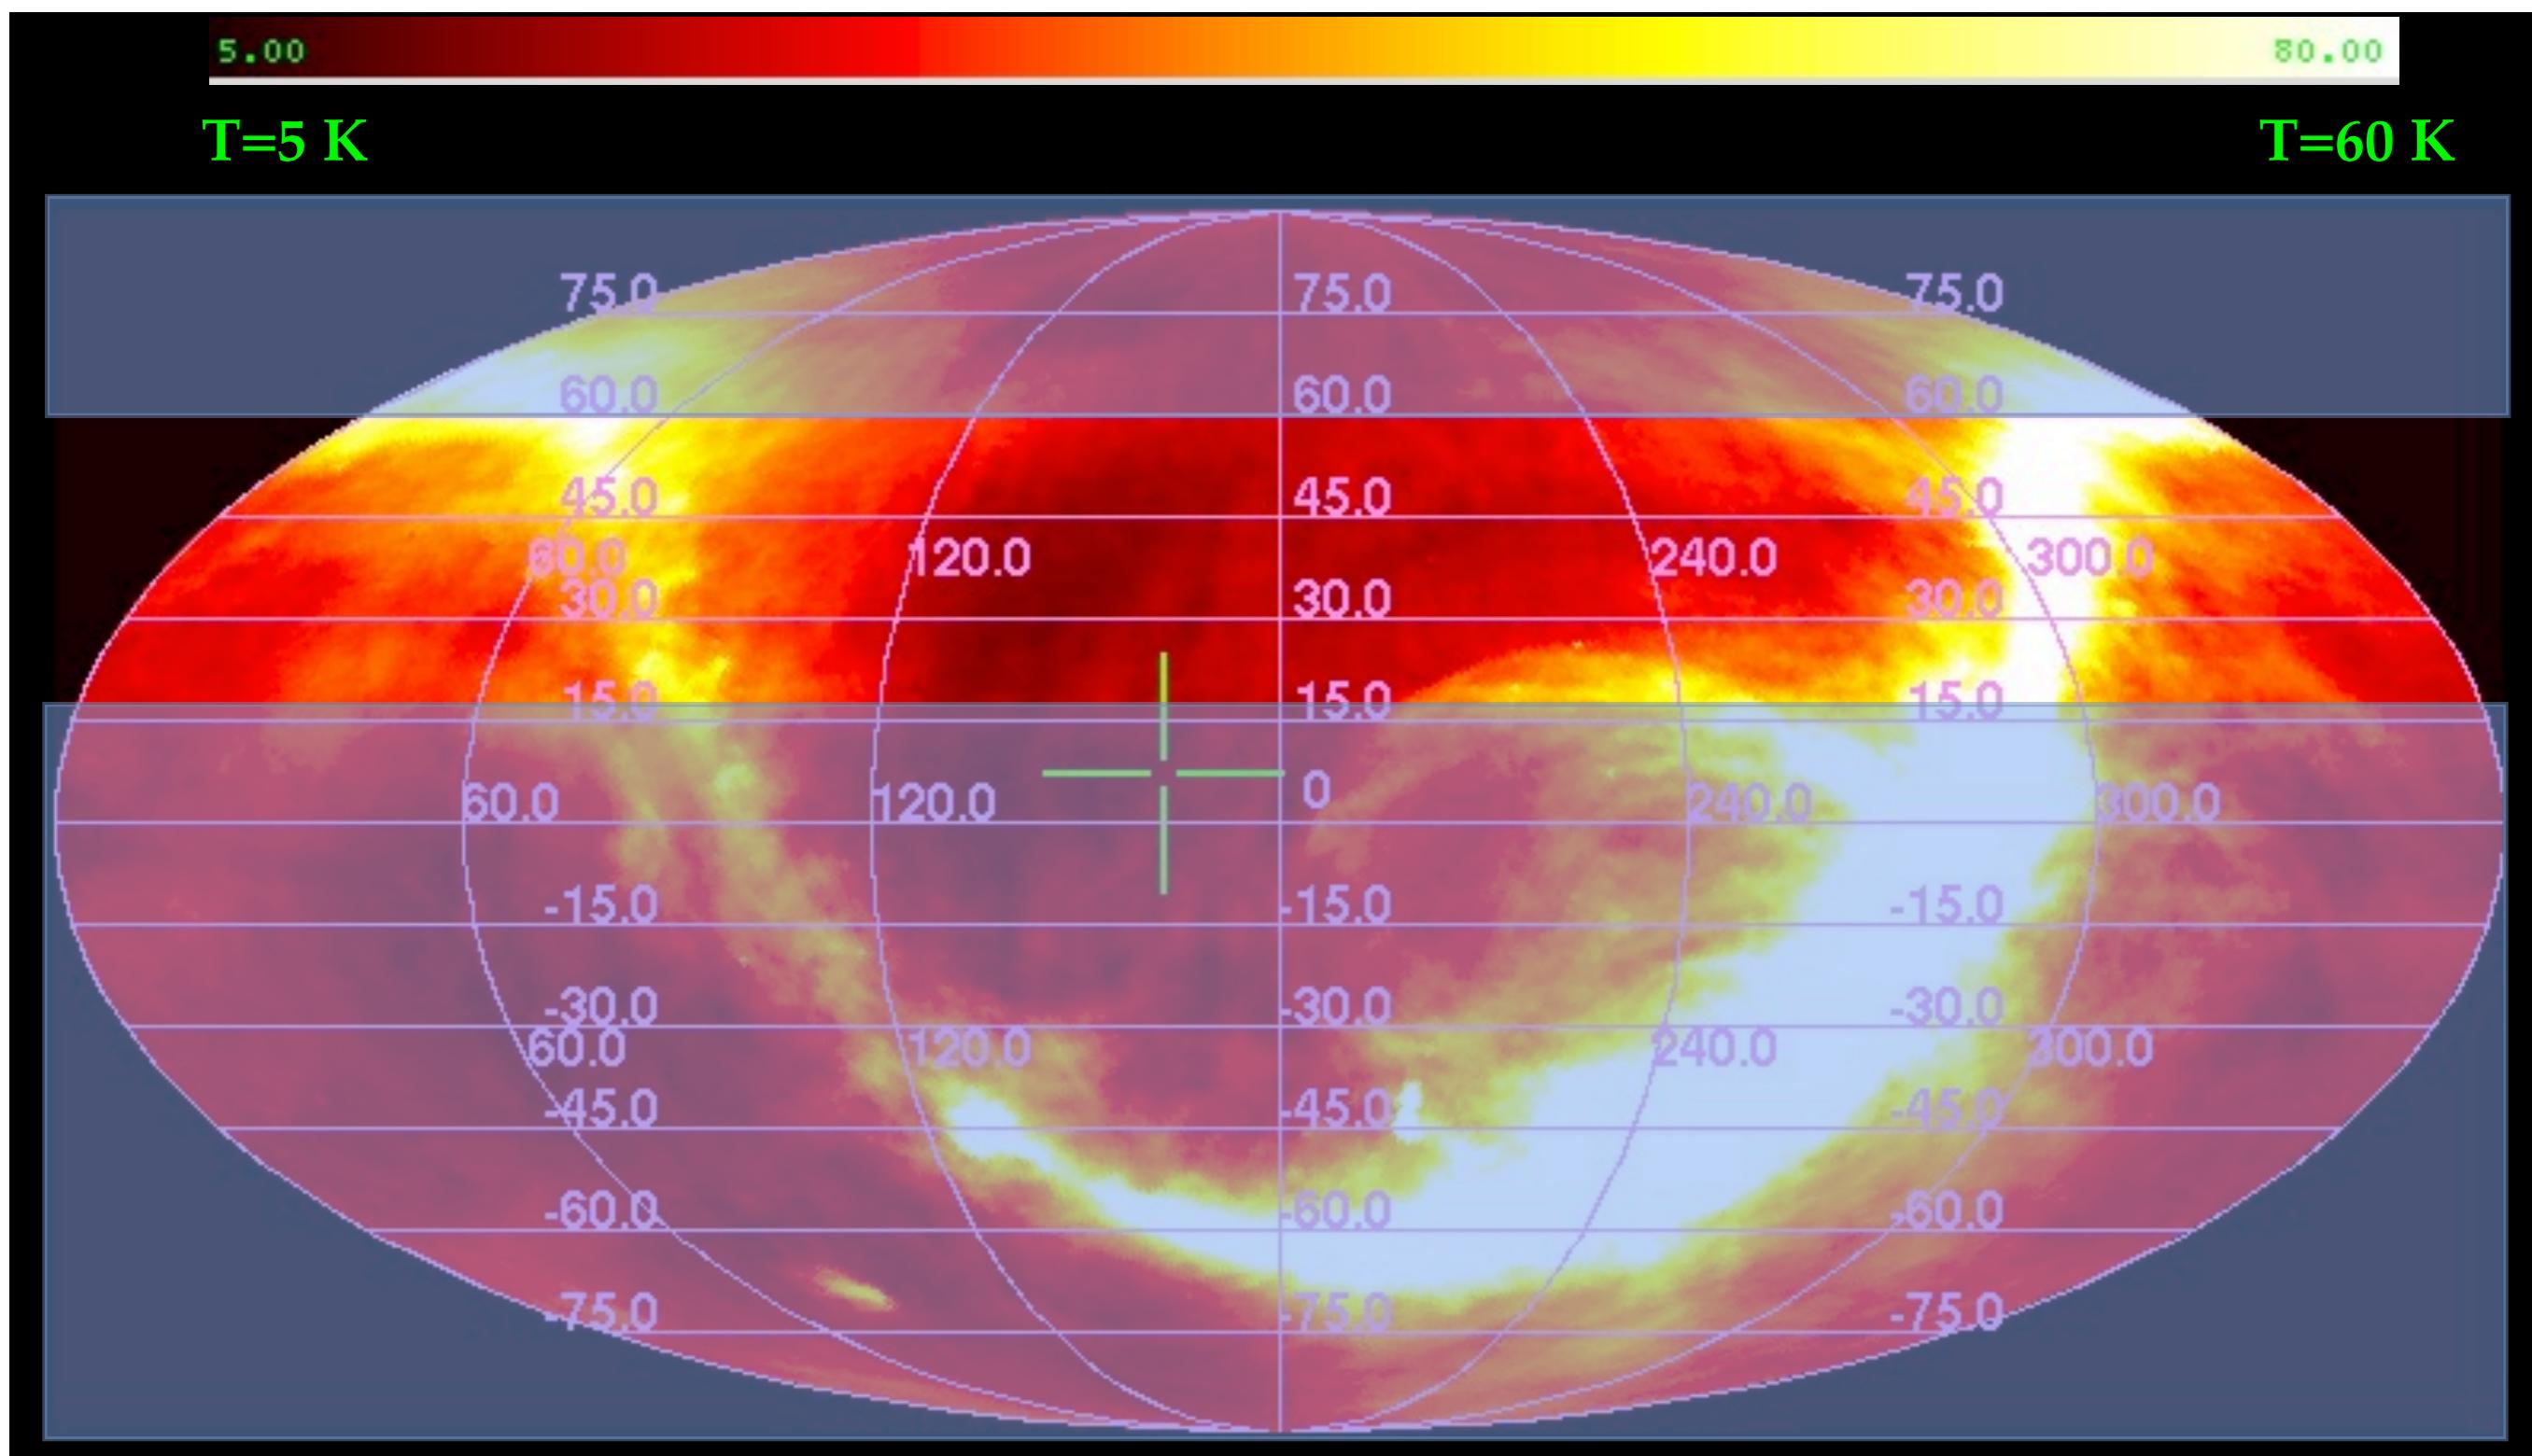

# CONFIGURATIONS

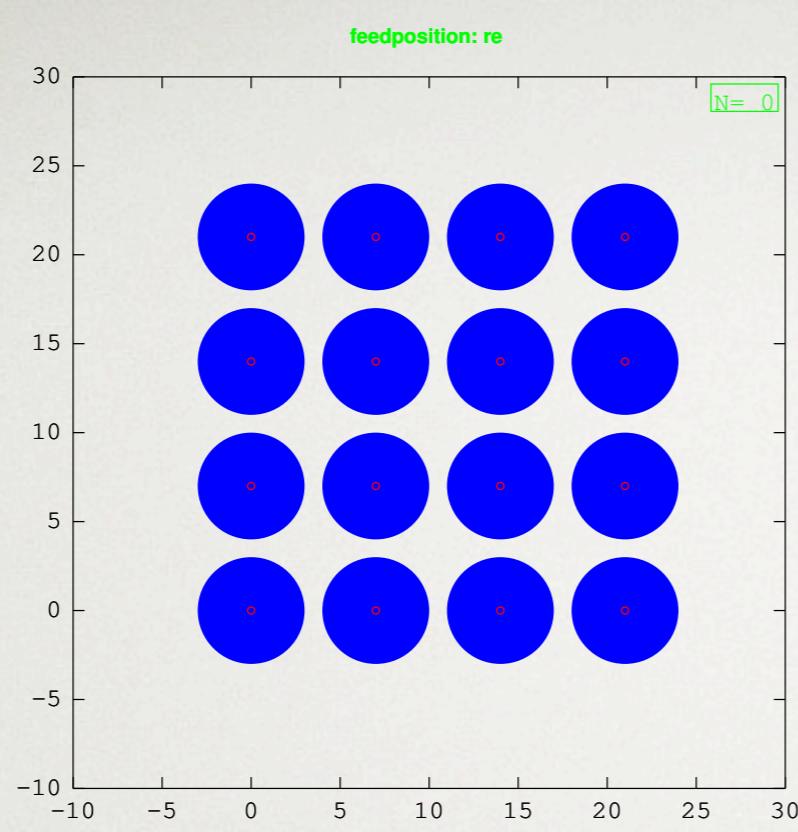

- $16=4 \times 4$   $D=6$  m dishes,  $D_{\text{eff}}=\eta D=5.4$  m, base spacing  $d=7$  m
- maximum  $N_B = 8 \times 17 = 136$  baselines
- (a) regular array,  $28 \times 28 \text{ m}^2$ ,  $N_B = 25$  baselines
- (b) circular,  $1+6+9$ ,  $\sim 32 \times 32 \text{ m}^2$ ,  $N_B = 101$  baselines
- (c) irregular,  $2+3+5+4+2$ ,  $\sim 32 \times 32 \text{ m}^2$ ,  $N_B = 84$  baselines
- 9 scans :  $\delta = \{0, \pm 1.5^\circ, \pm 3^\circ, \pm 4.5^\circ, \pm 6^\circ\}$

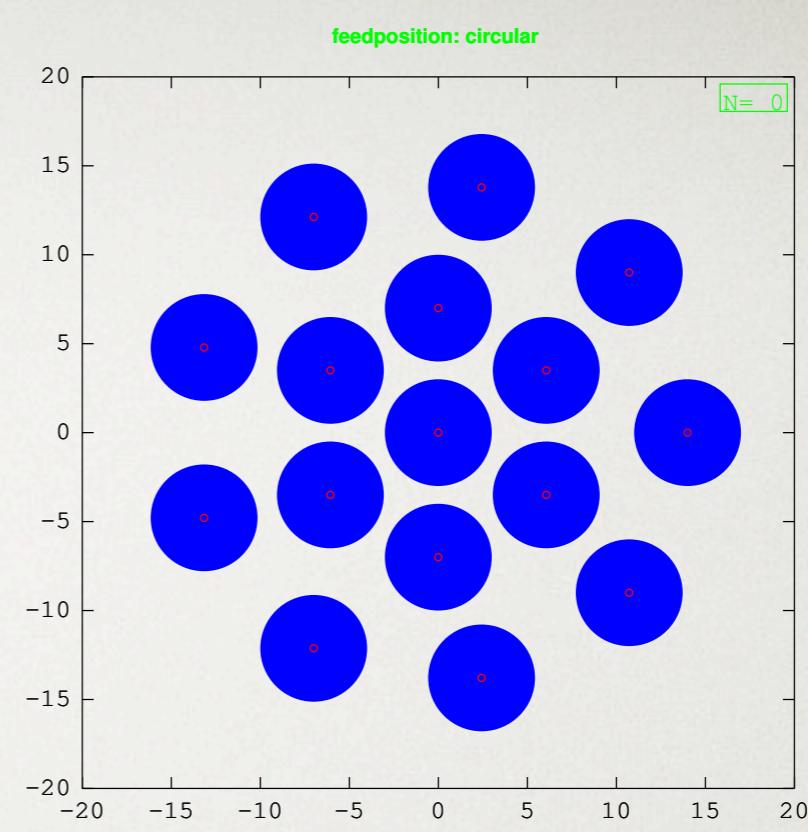

$$d \simeq \frac{D}{\cos(\beta_{max})}$$
$$D = 6 \text{ m}, d = 7 \text{ m}$$
$$\beta_{max} \simeq 30^\circ$$

Synchrotron map @ 400 MHz - Eq. Coordinates (ra,dec)  
Tianlai-16dish accessible sky region  
(45 N  $\pm$  25 deg)  $\rightarrow$   $20 < \delta < 60$  in Xinjiang (45 N)

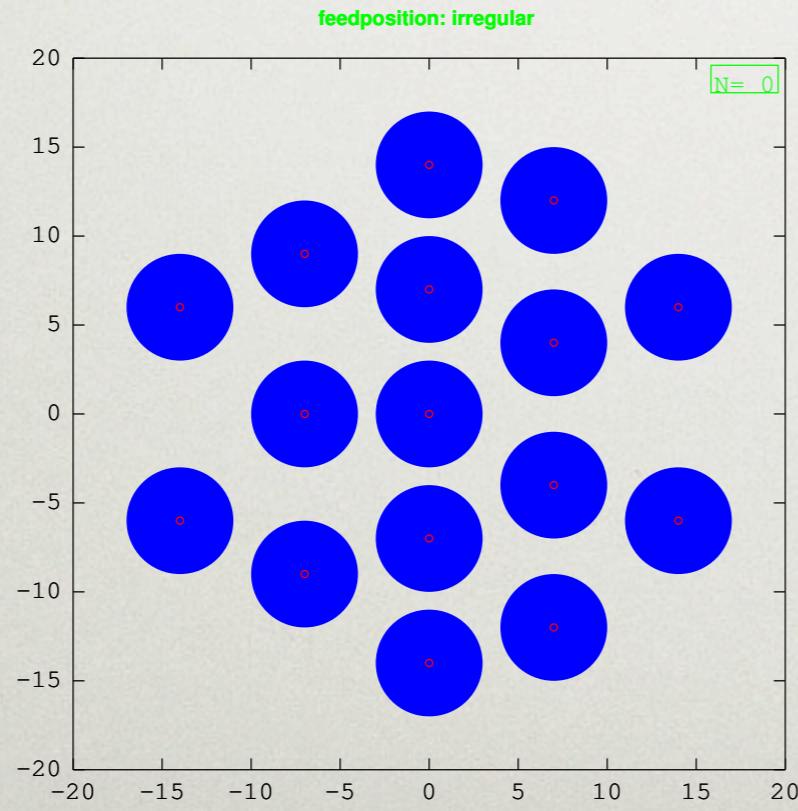

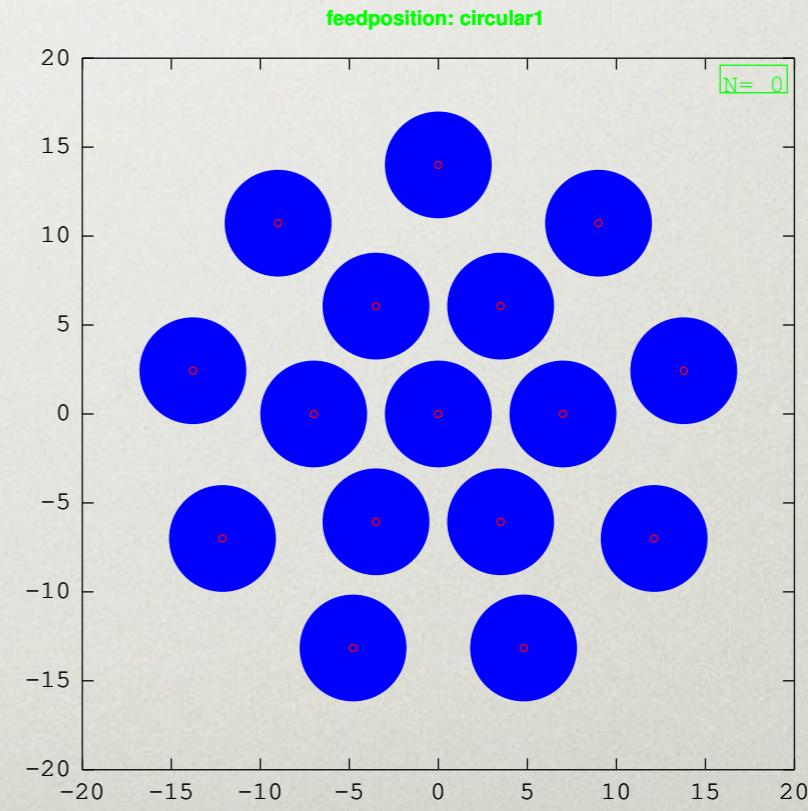

(a) regular

(b) circular

(c) irrgular

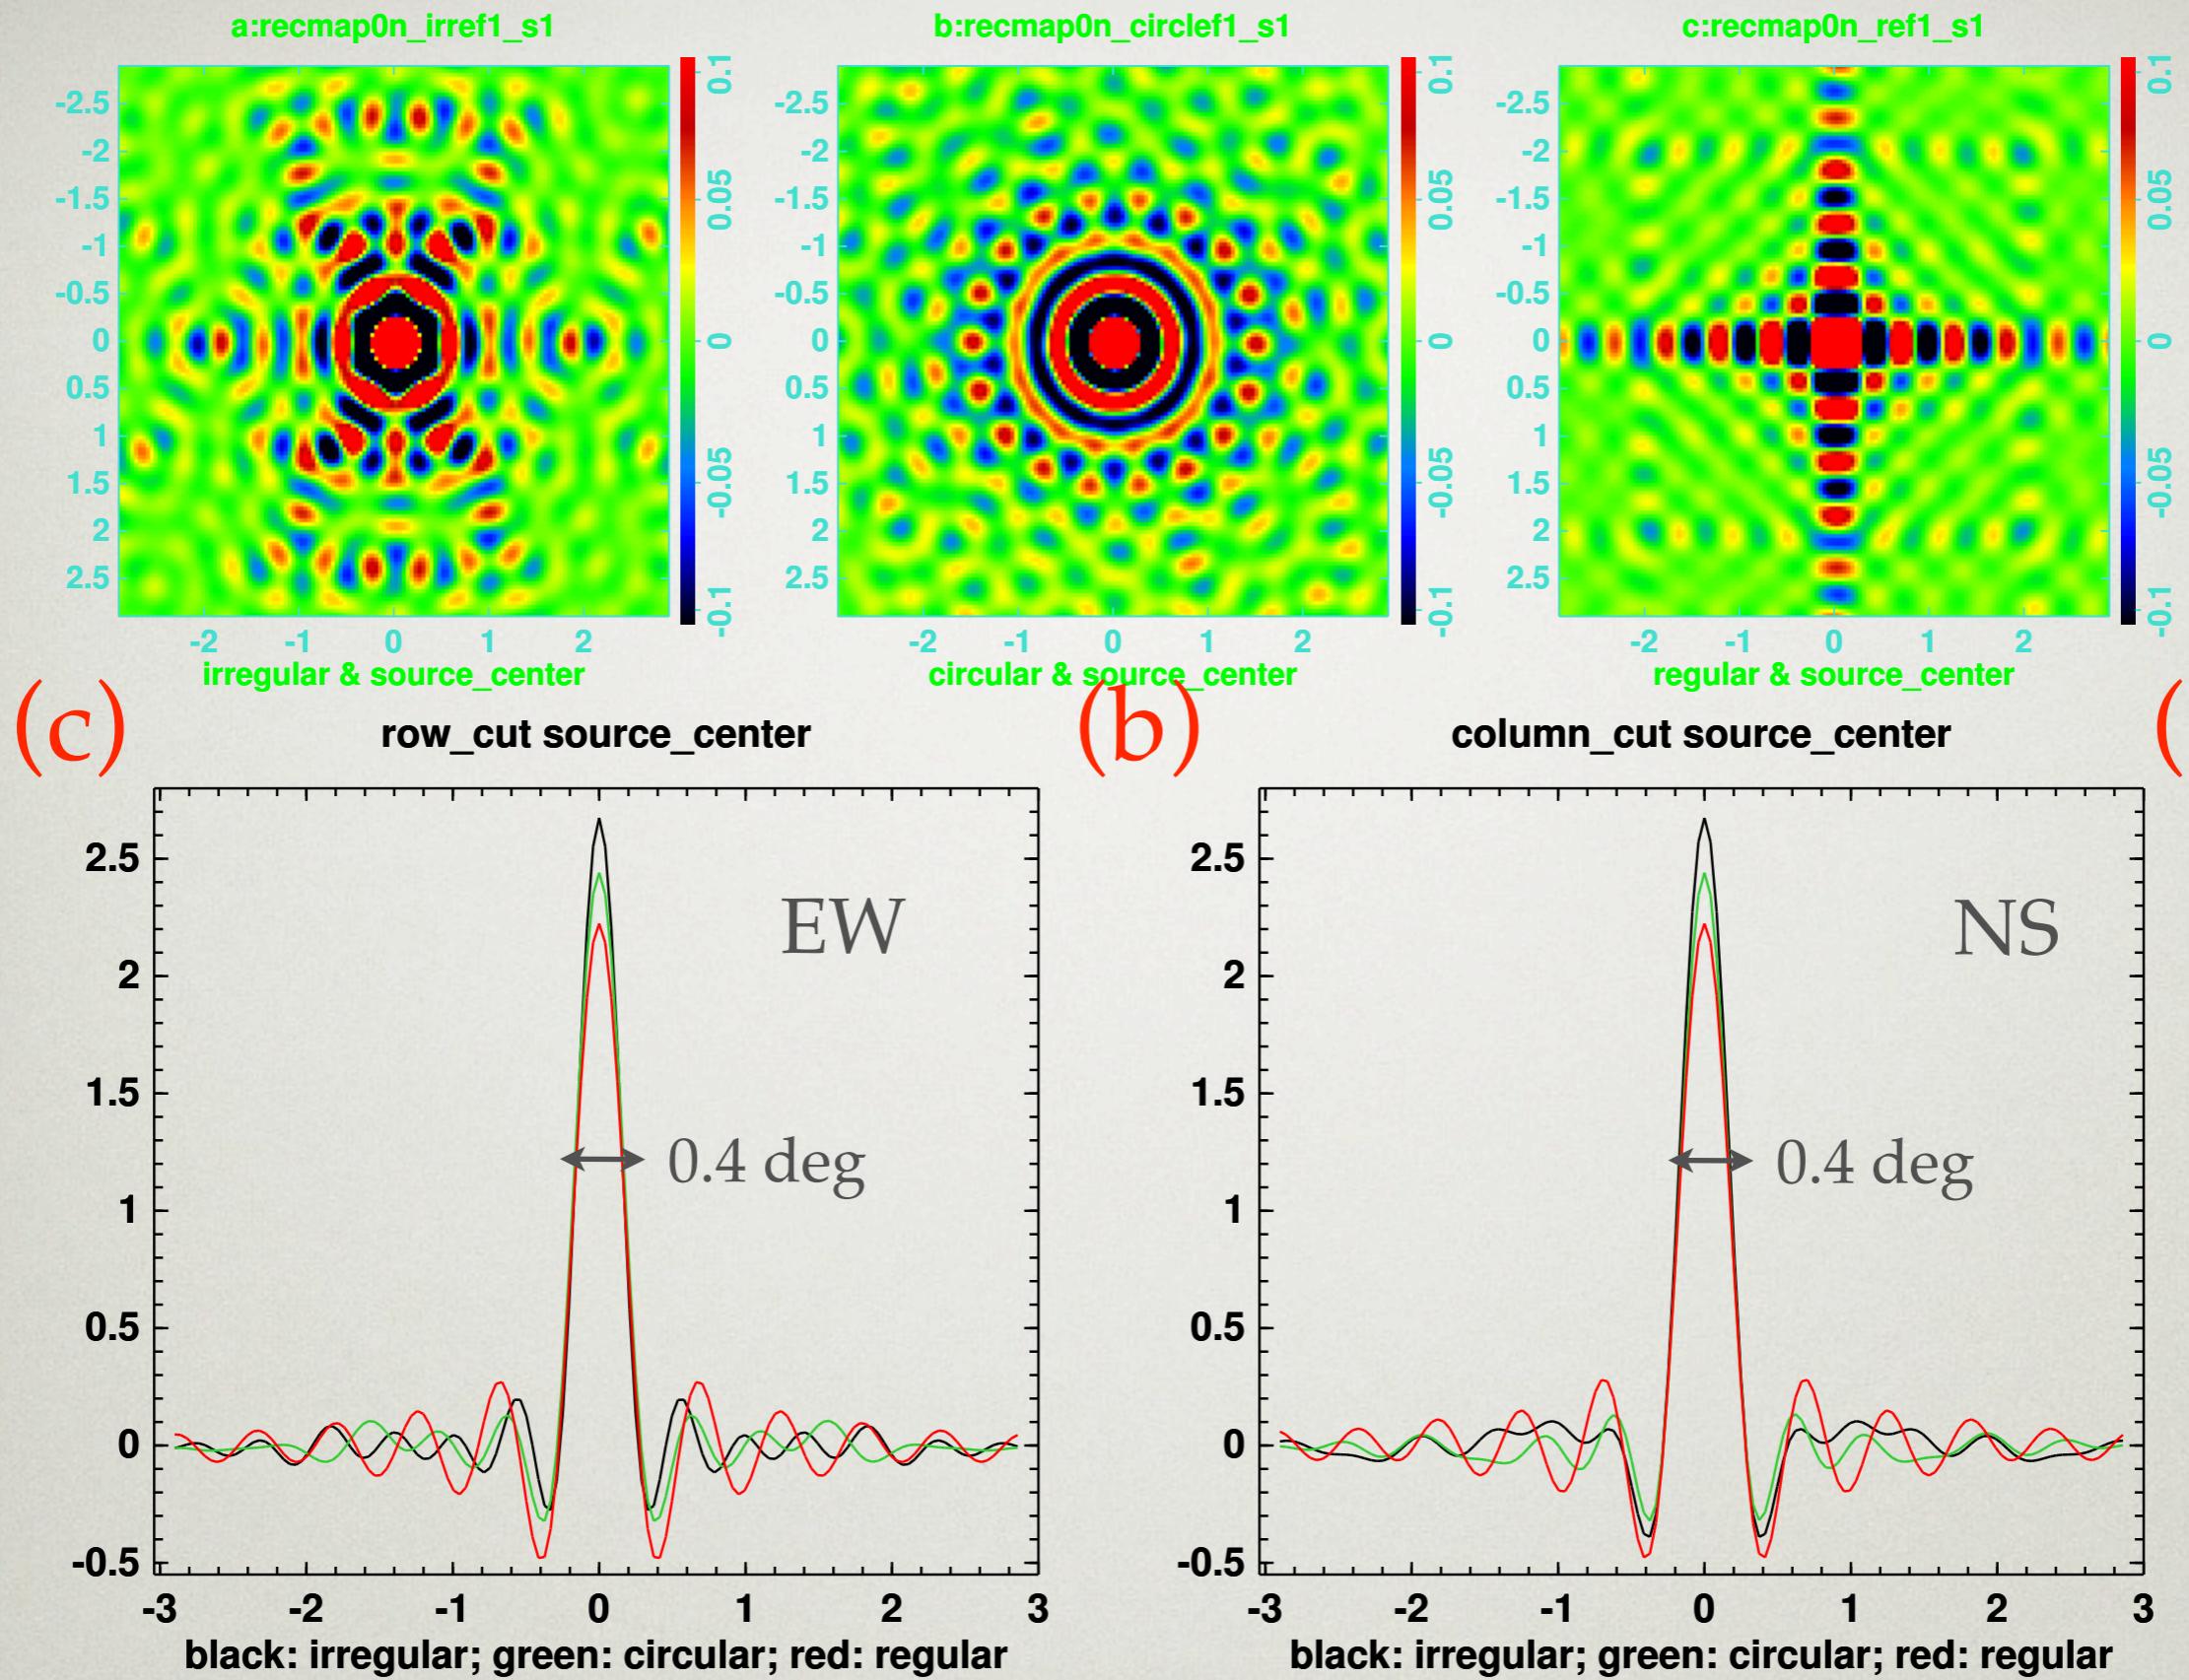

(d) circular-rotated

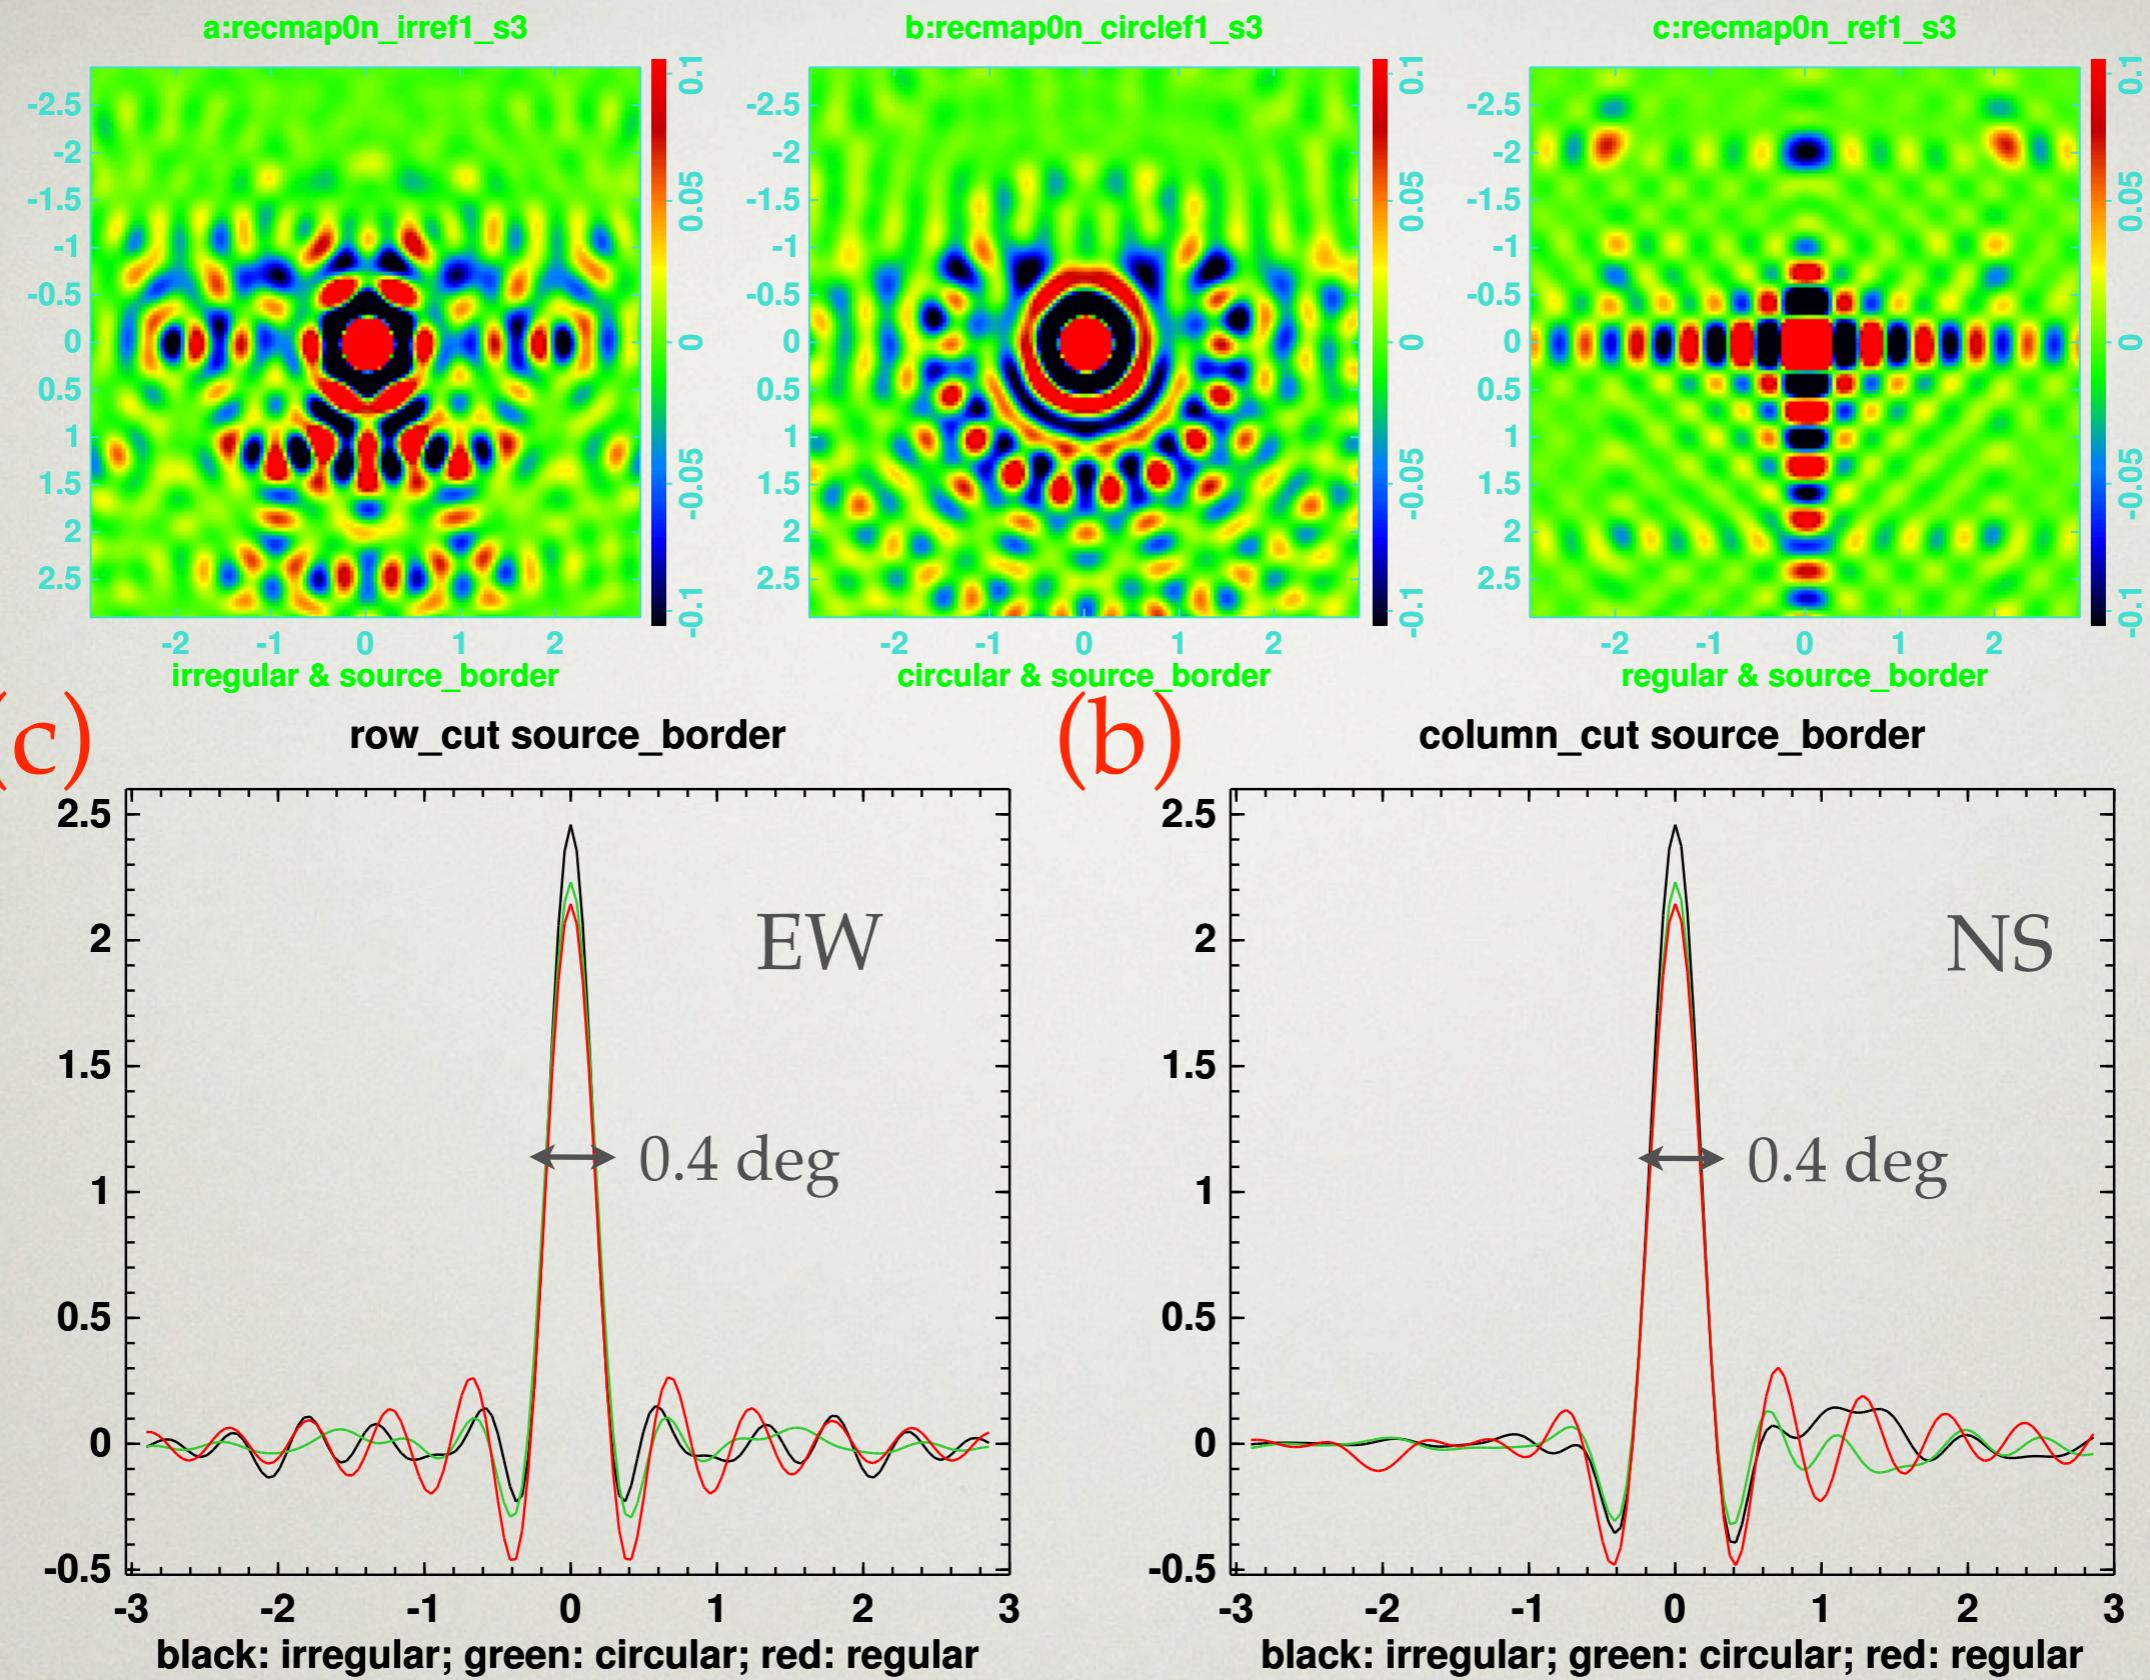

# BEAM SHAPES

---

- Compute the reconstructed from the visibilities (without noise) for an input map with point sources at different declination
- The beam (response to a point source) depends on declination, but not on RA
- beam before and after applying weights on the  $(u,v)$  plane (cut/weight based on the computed noise covariance matrix, application of a frequency independent global beam)

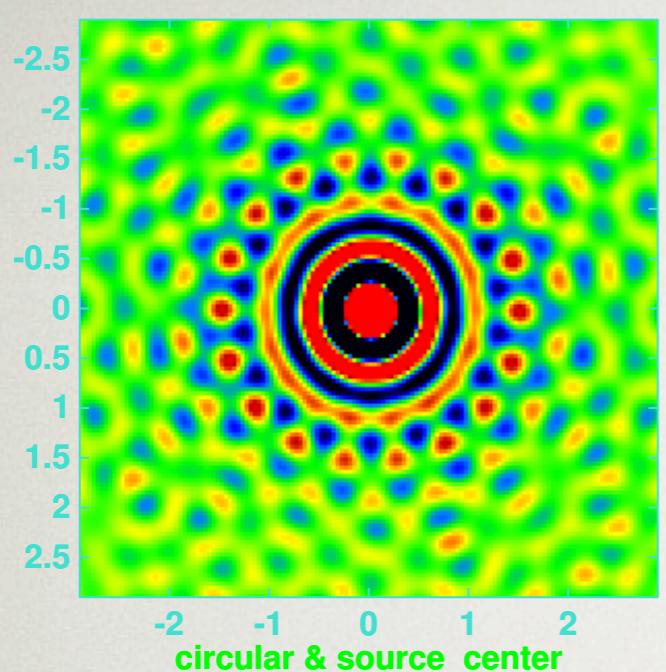

Beam at center (in  $\delta$ ) - 1200 MHz

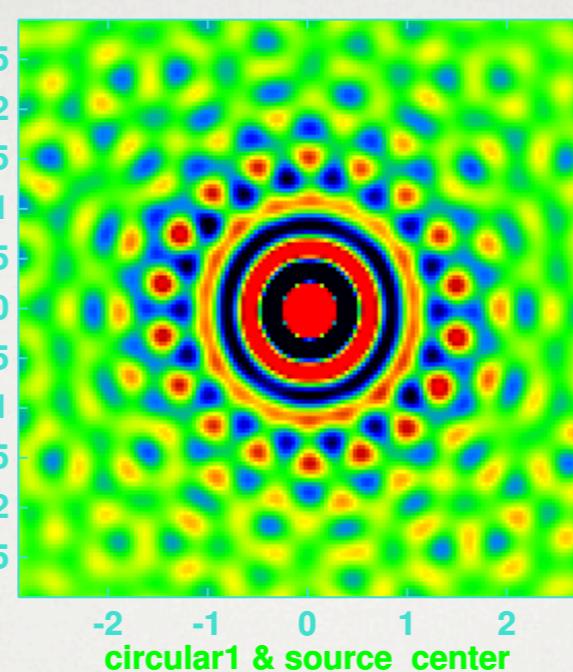

Beam at the edge (in  $\delta$ ) - 1200 MHz

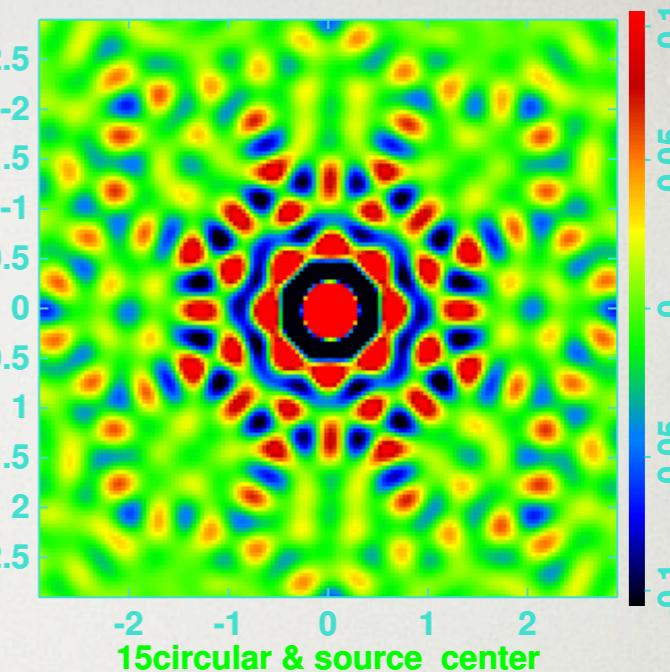

a:recmap0n\_circlef1\_s1

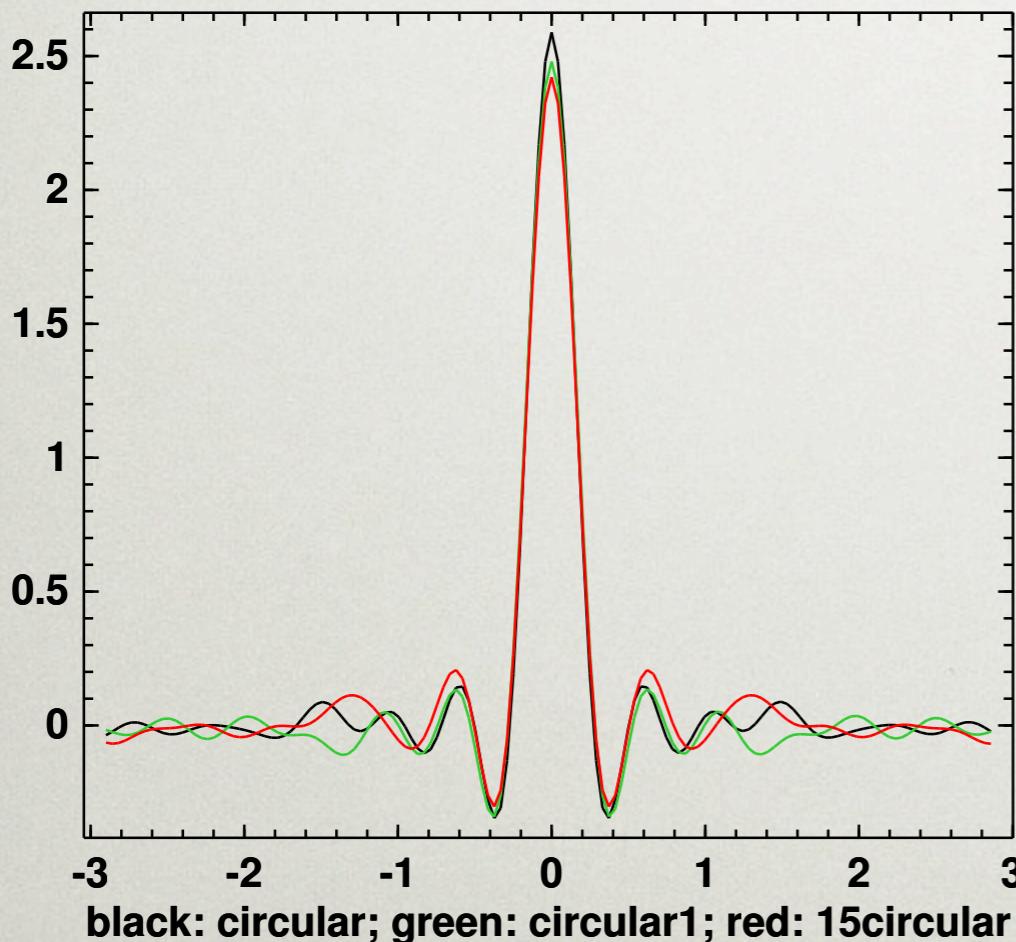

b:recmap0n\_circle1f1\_s1

c:recmap0n\_15circlef1\_s1

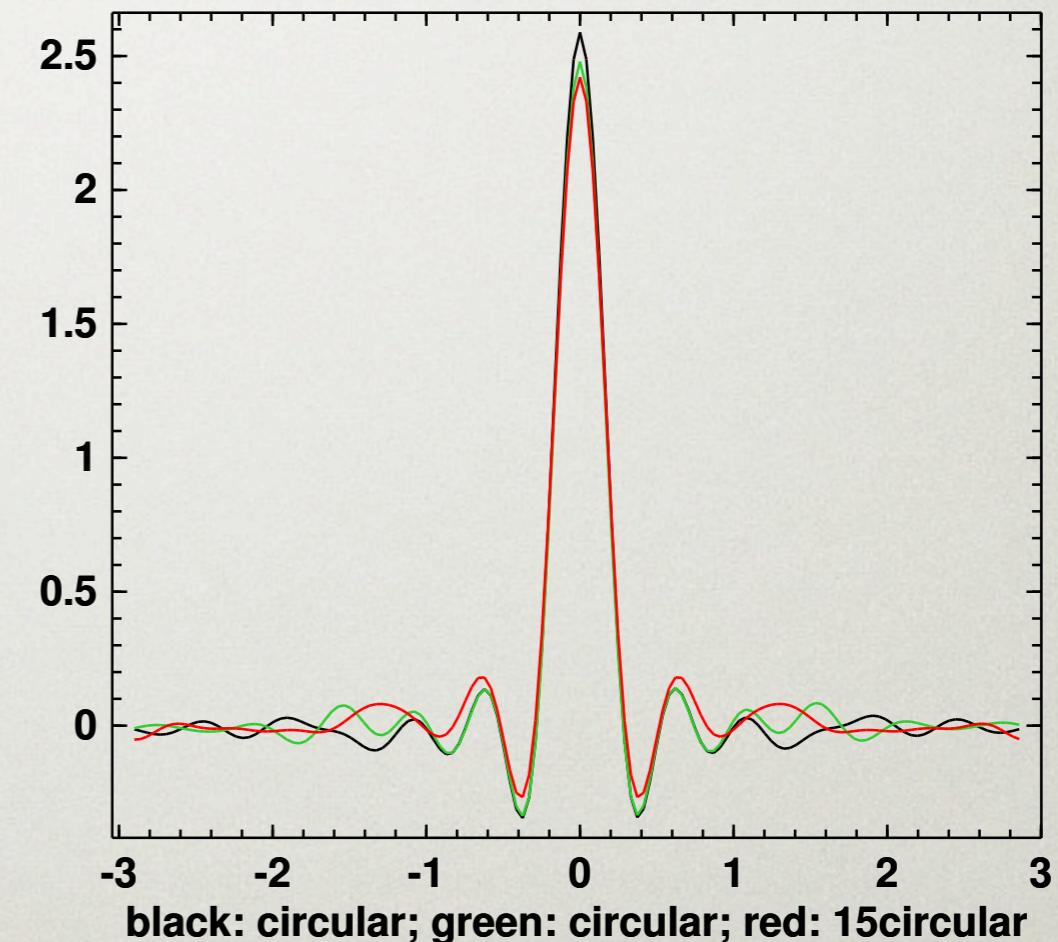

row\_cut source\_center

black: circular; green: circular1; red: 15circular

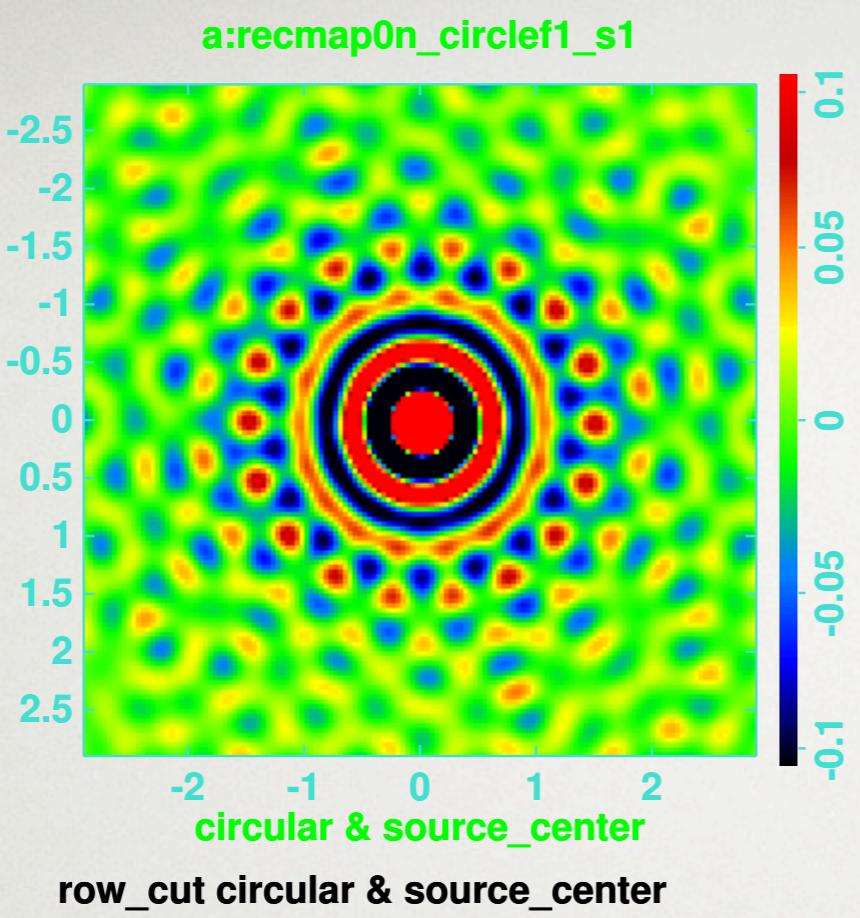

column\_cut source\_center

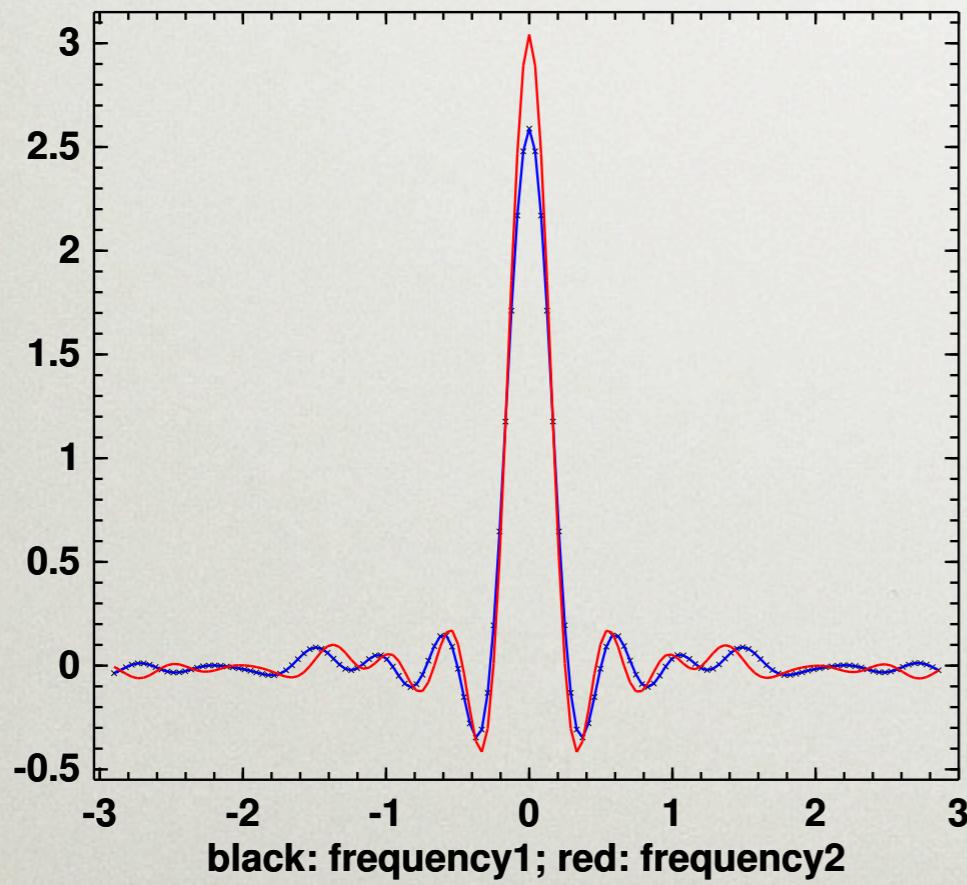

black: circular; green: circular1; red: 15circular

Beam at center for 2 16-dish circular  
configurations and one 15-dish circular

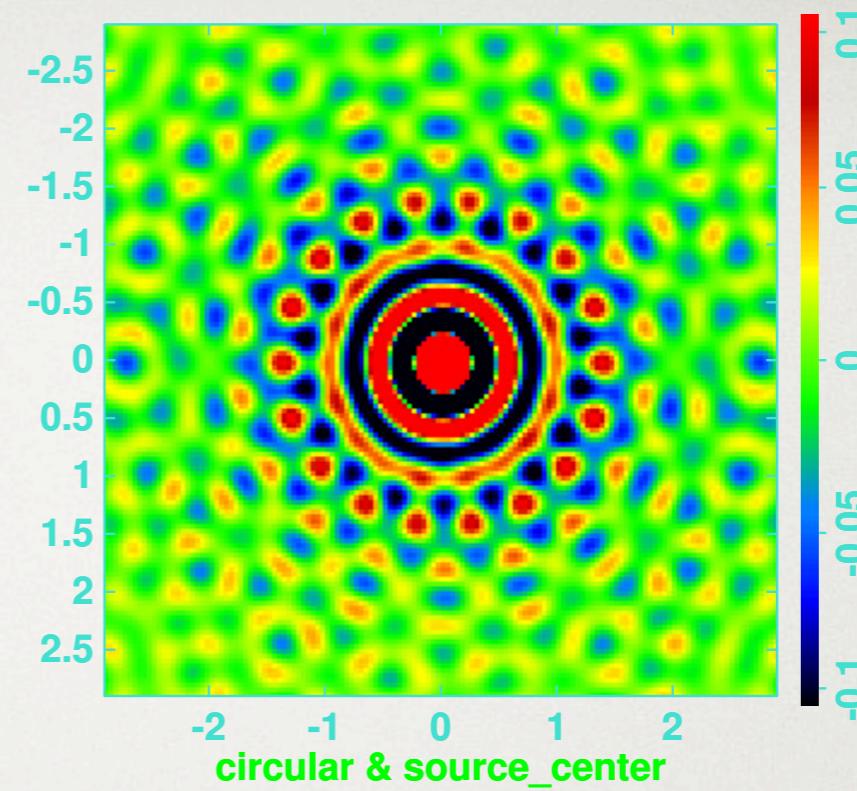

1200 MHz

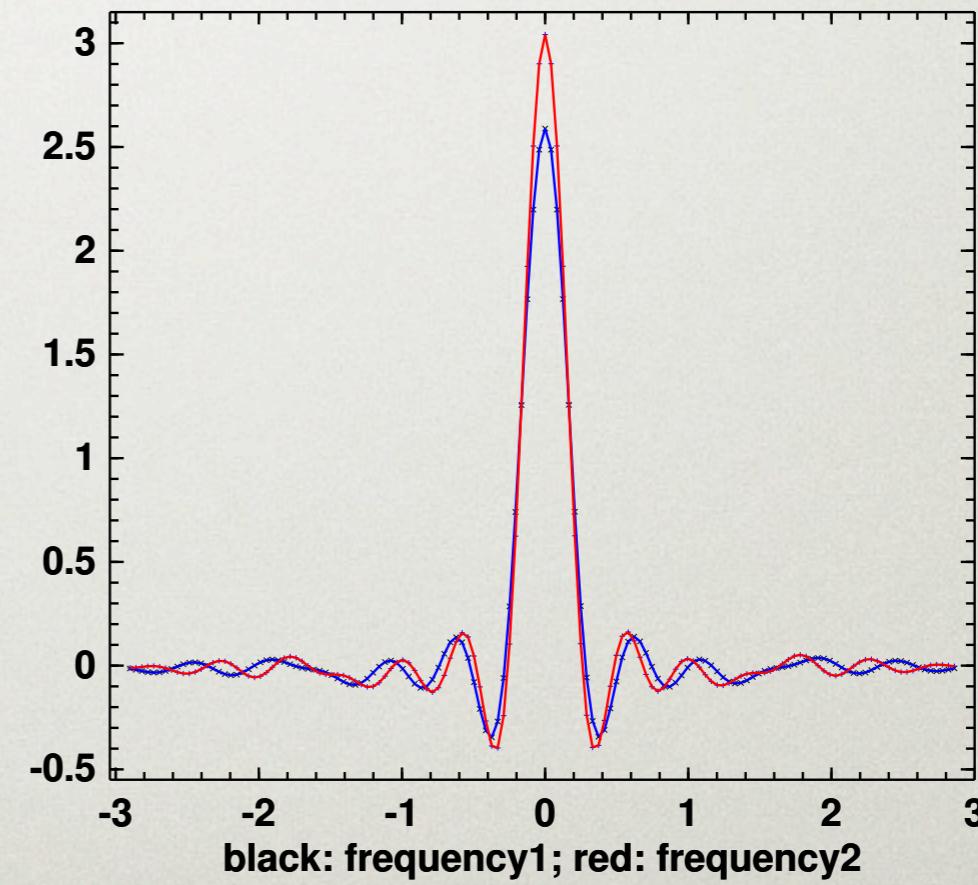

row\_cut circular & source\_center

b:recmap0n\_circlef2\_s1

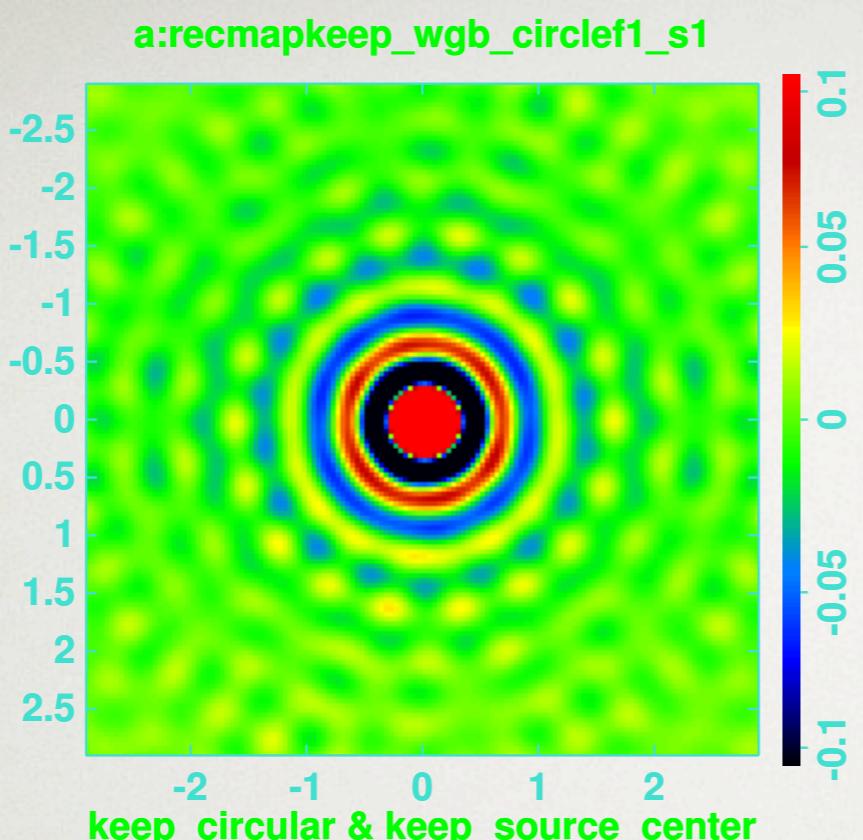

column\_cut circular & source\_center

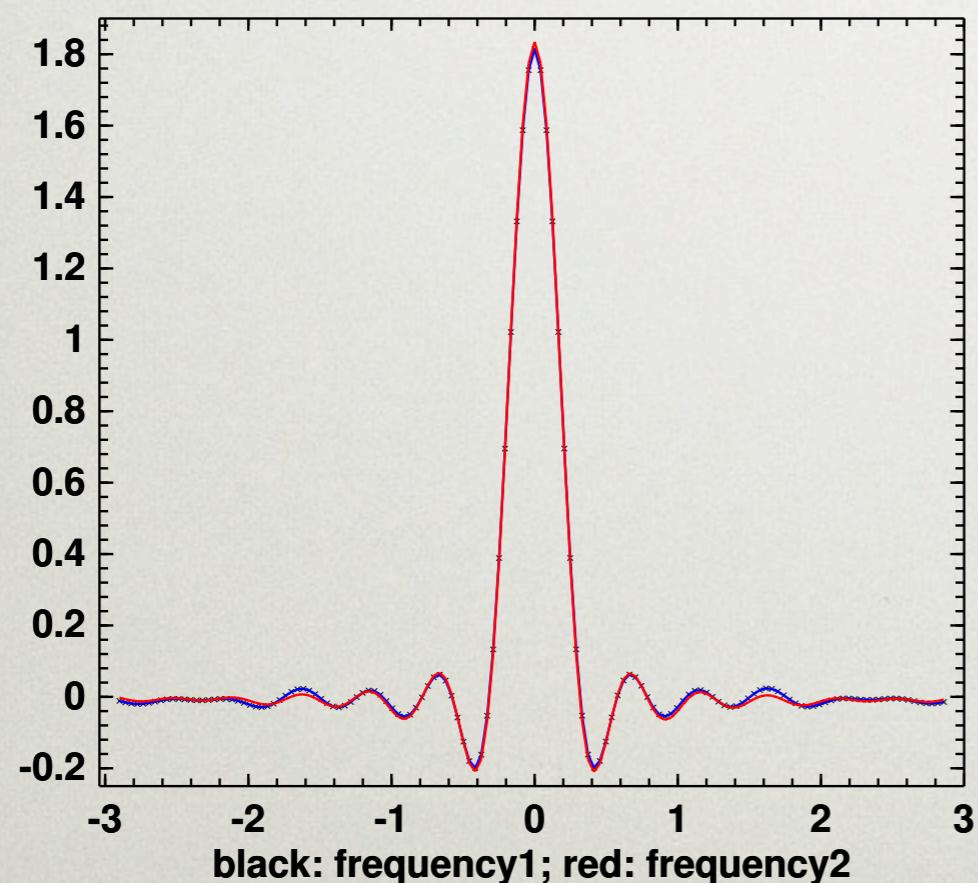

1300 MHz

Beam frequency dependency - circular  
configuration (b) - 1200 MHz, 1300 MHz

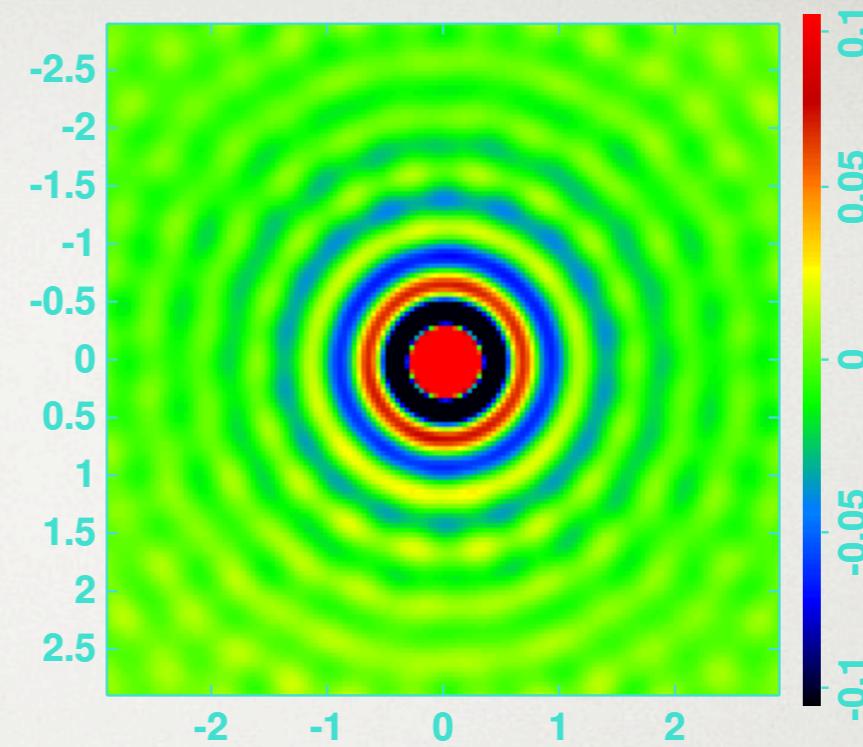

1200 MHz

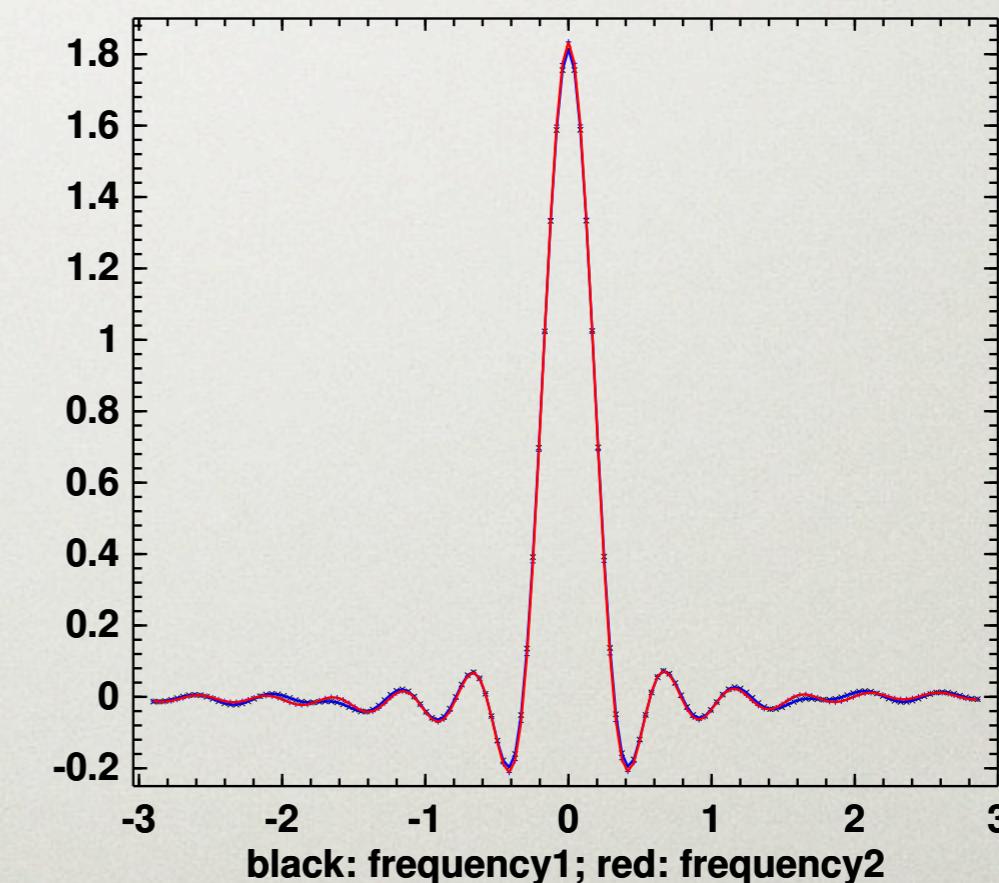

row\_cut keep\_circular & keep\_source\_center

b:recmapkeep\_wgb\_circleft2\_s1

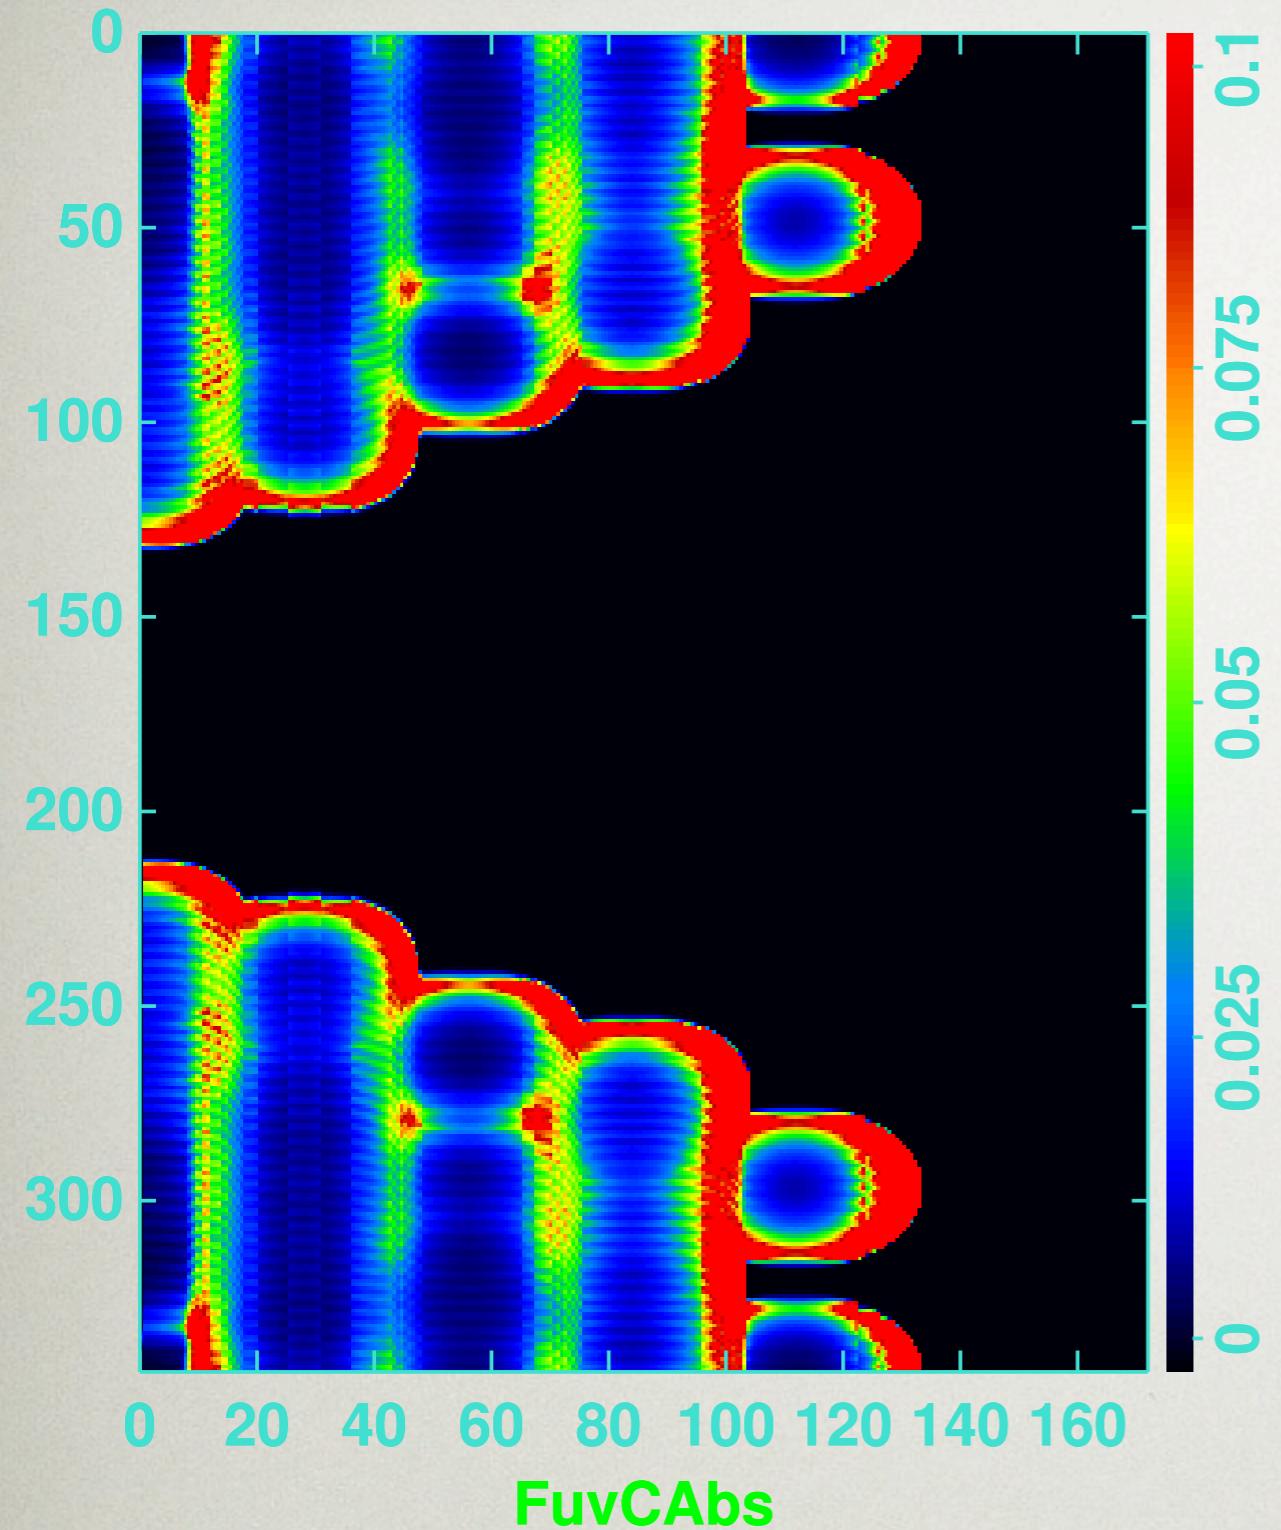

1300 MHz

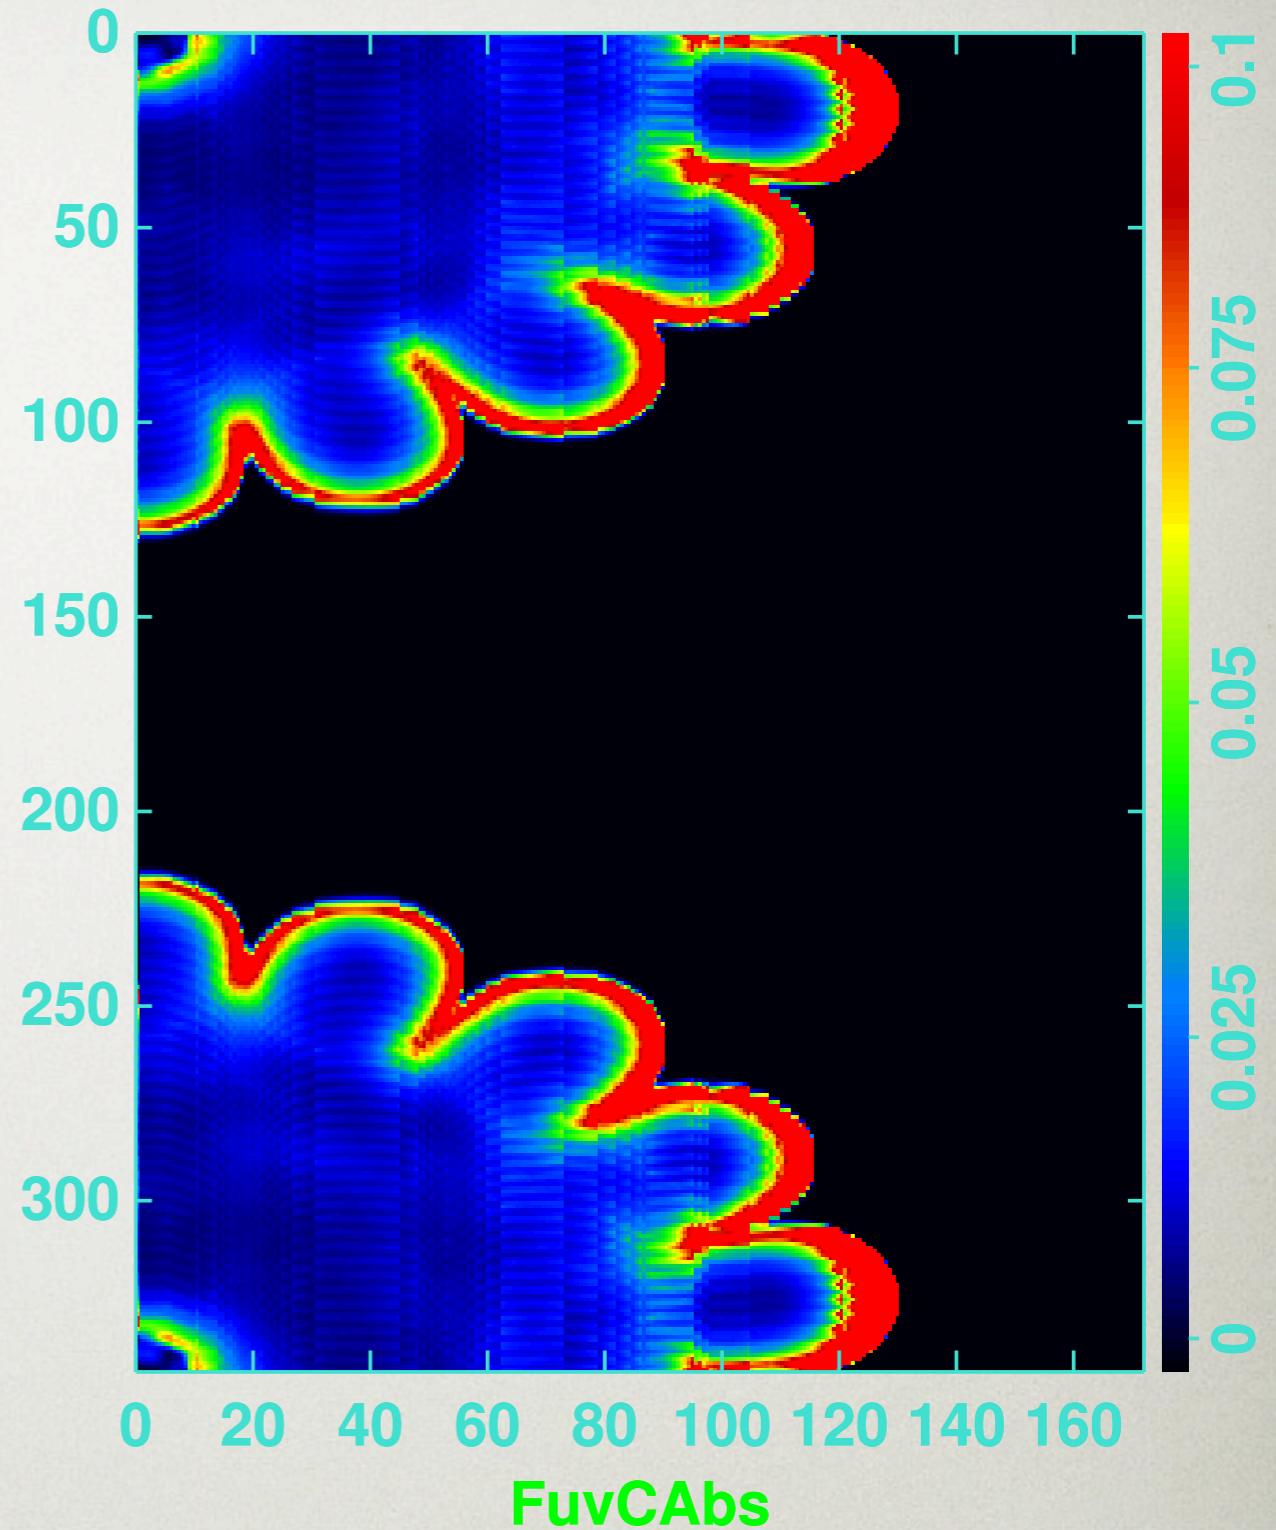

Applying a global weight function - circular configuration (b) - 1200 MHz, 1300 MHz

irregular

circular

Diagonal of the error covariance matrix for configurations (b),(c)

# TRANSFER FUNCTION AND NOISE POWER SPECTRUM

---

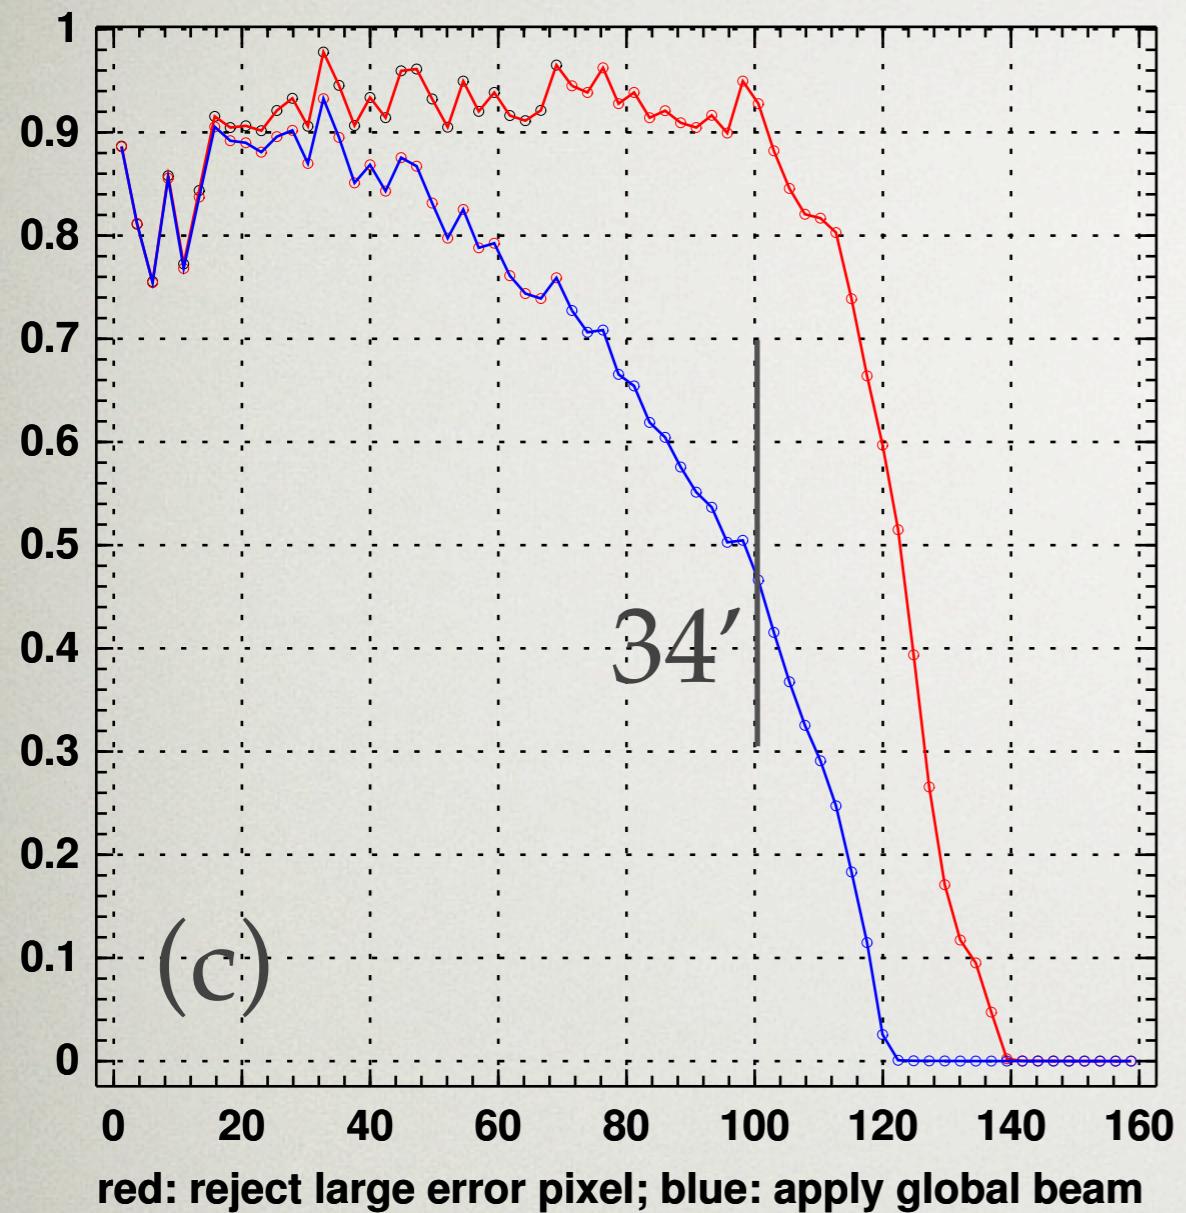

- $T(t_{\perp})$ : Compute the reconstructed map for a white noise input map, compute the power spectrum of the reconstructed map
- Noise power spectrum: reconstruct the map with the visibility noise only ( $F(u,v)=0$ ) and compute the power spectrum
- take the average over several input noise map / visibility noise realizations (single / few realizations right now)

$$t_{\perp} = \sqrt{u^2 + v^2}$$

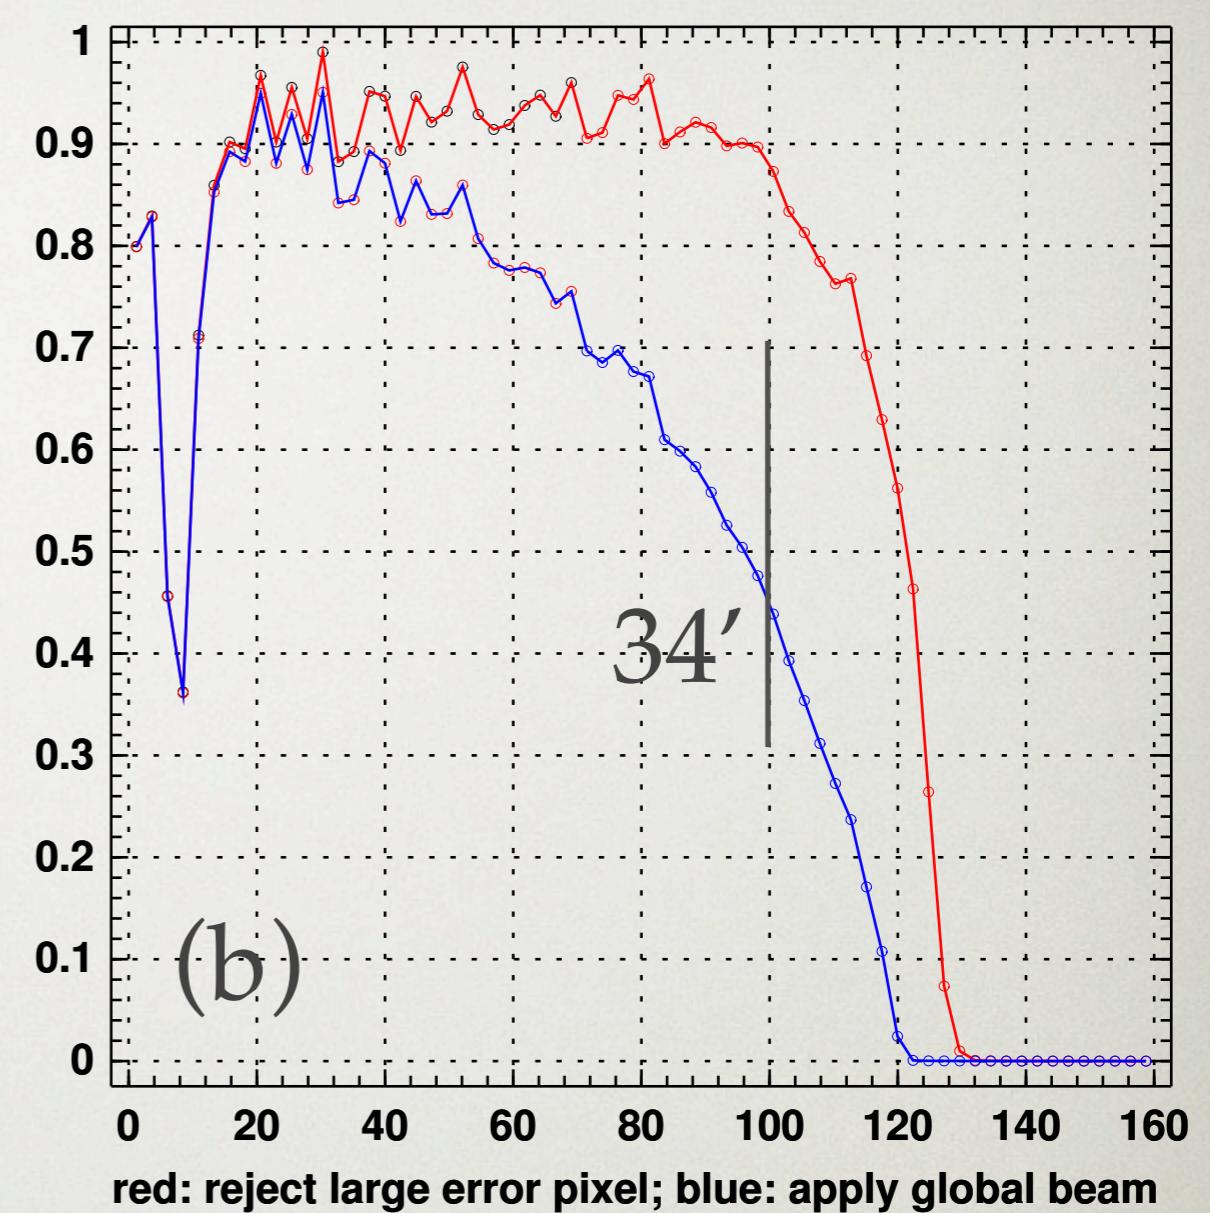

$$T(t_{\perp}) = \frac{P_{rec}(t_{\perp})}{P_{in}(t_{\perp})}$$

$$P_{noise}(t_{\perp}) = P_{noise-V}(t_{\perp})$$

**transfer function for irre array**

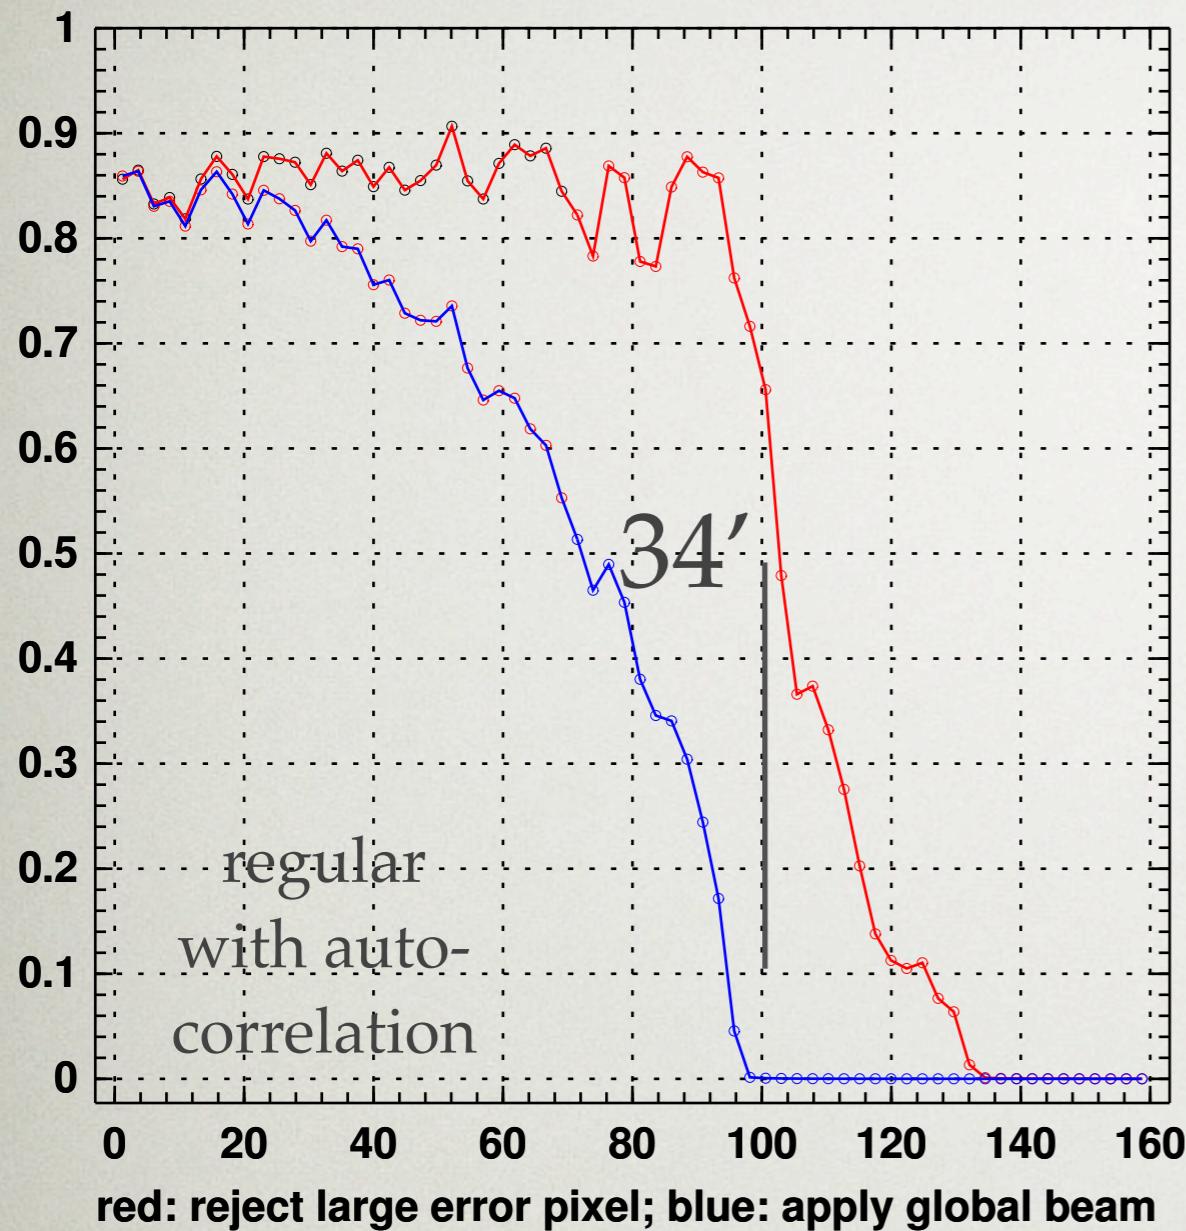

**transfer function for circle array**

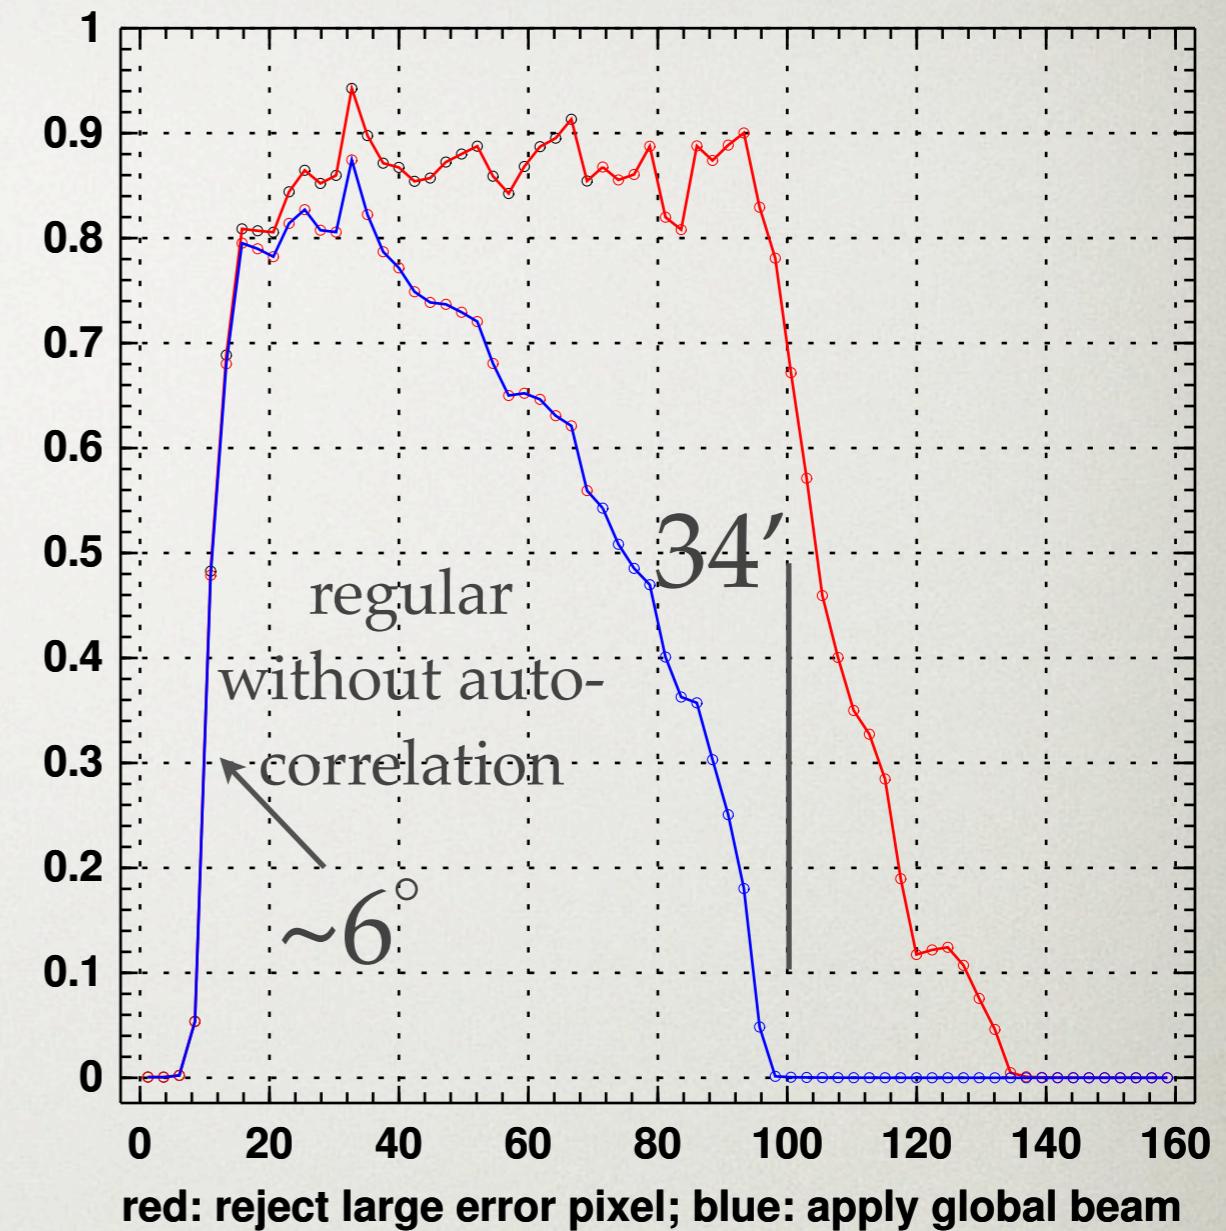

Transfer function for configurations (c)-irregular and (b)-circular rejecting high noise-variance modes (red), and with global beam weighting (blue)

**transfer function for re array**

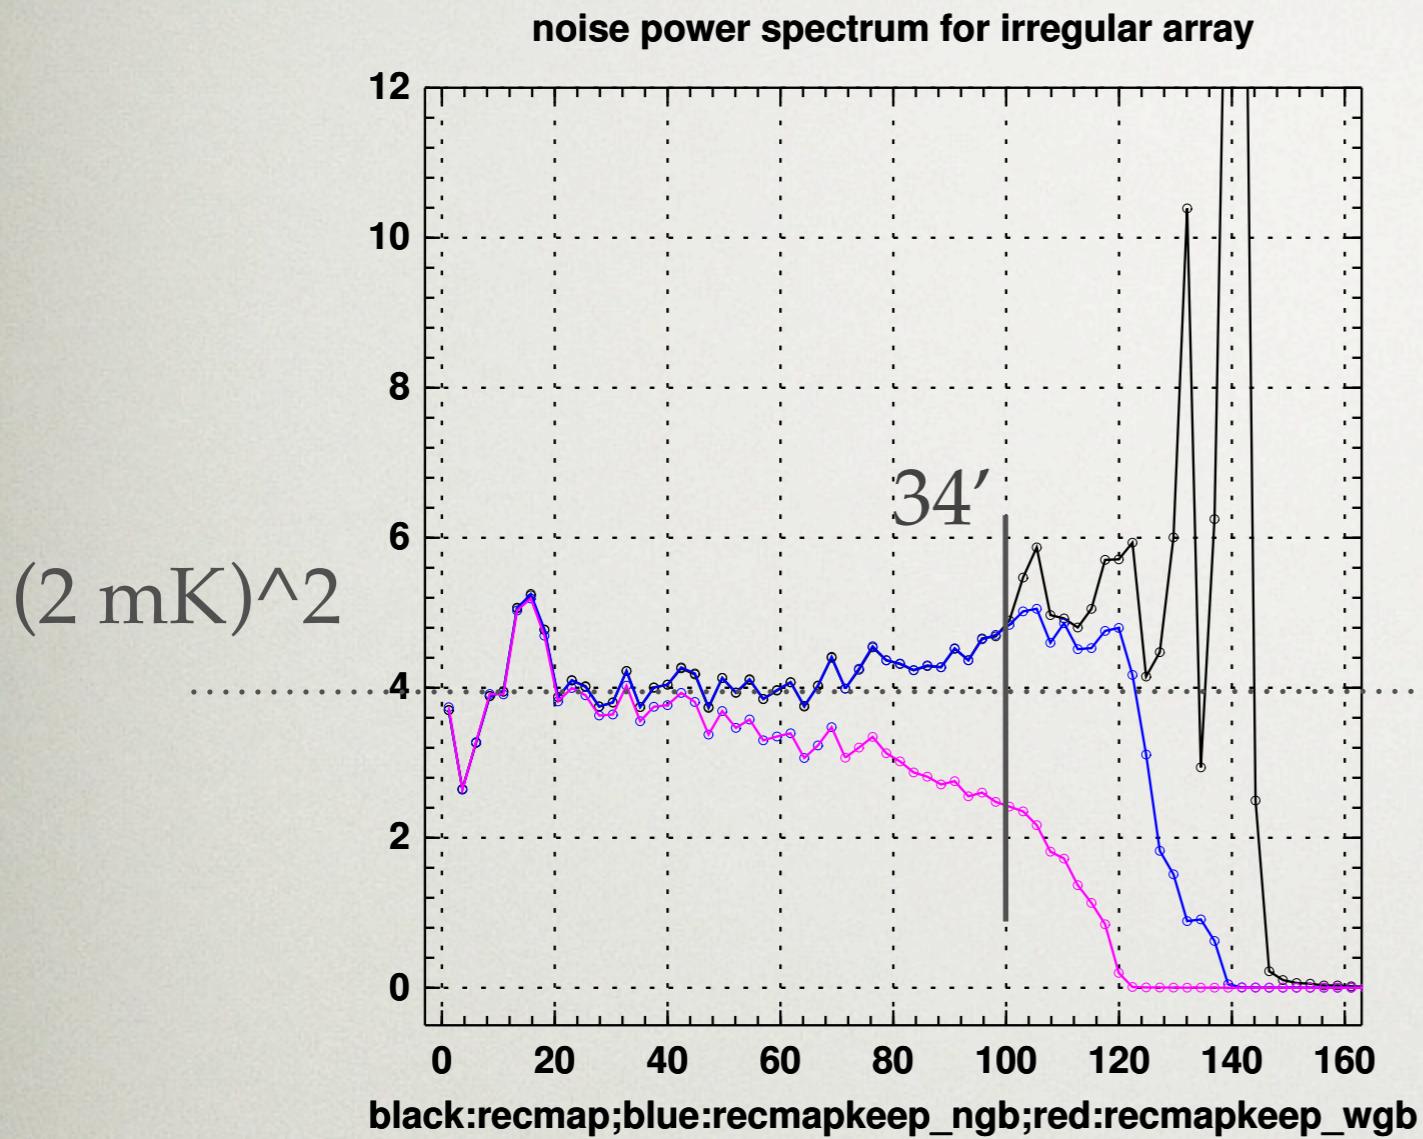

**transfer function for regular\_without\_autocor array**

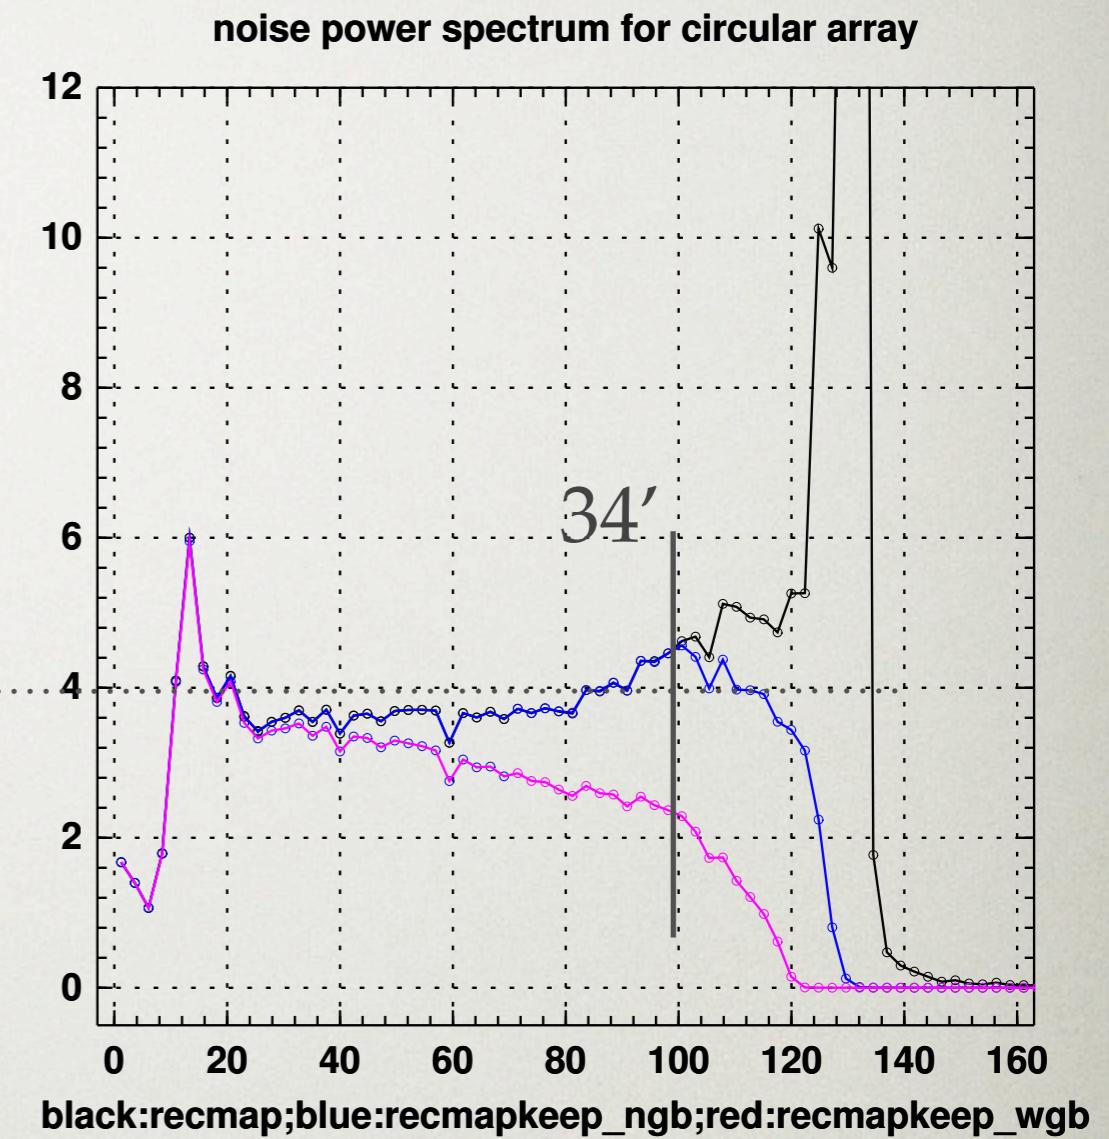

Transfer function for configurations the  
regular array - with/without autocorrelations  
rejecting high noise-variance modes (red),  
and global beam weighting (blue)

# Irregular array (c)

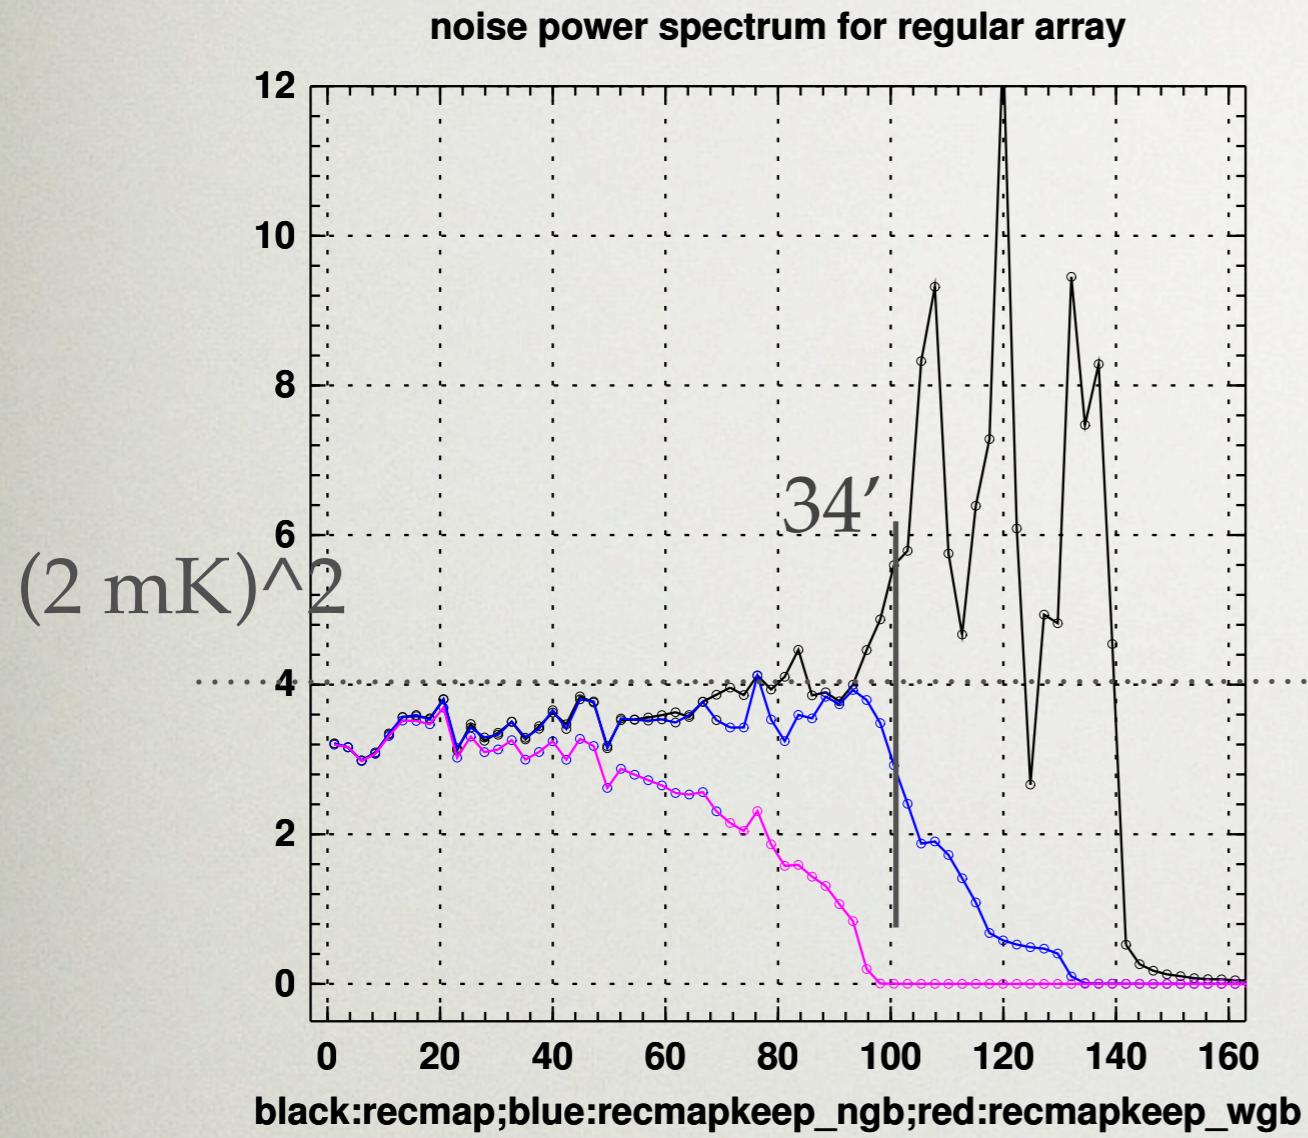

# Circular array (b)

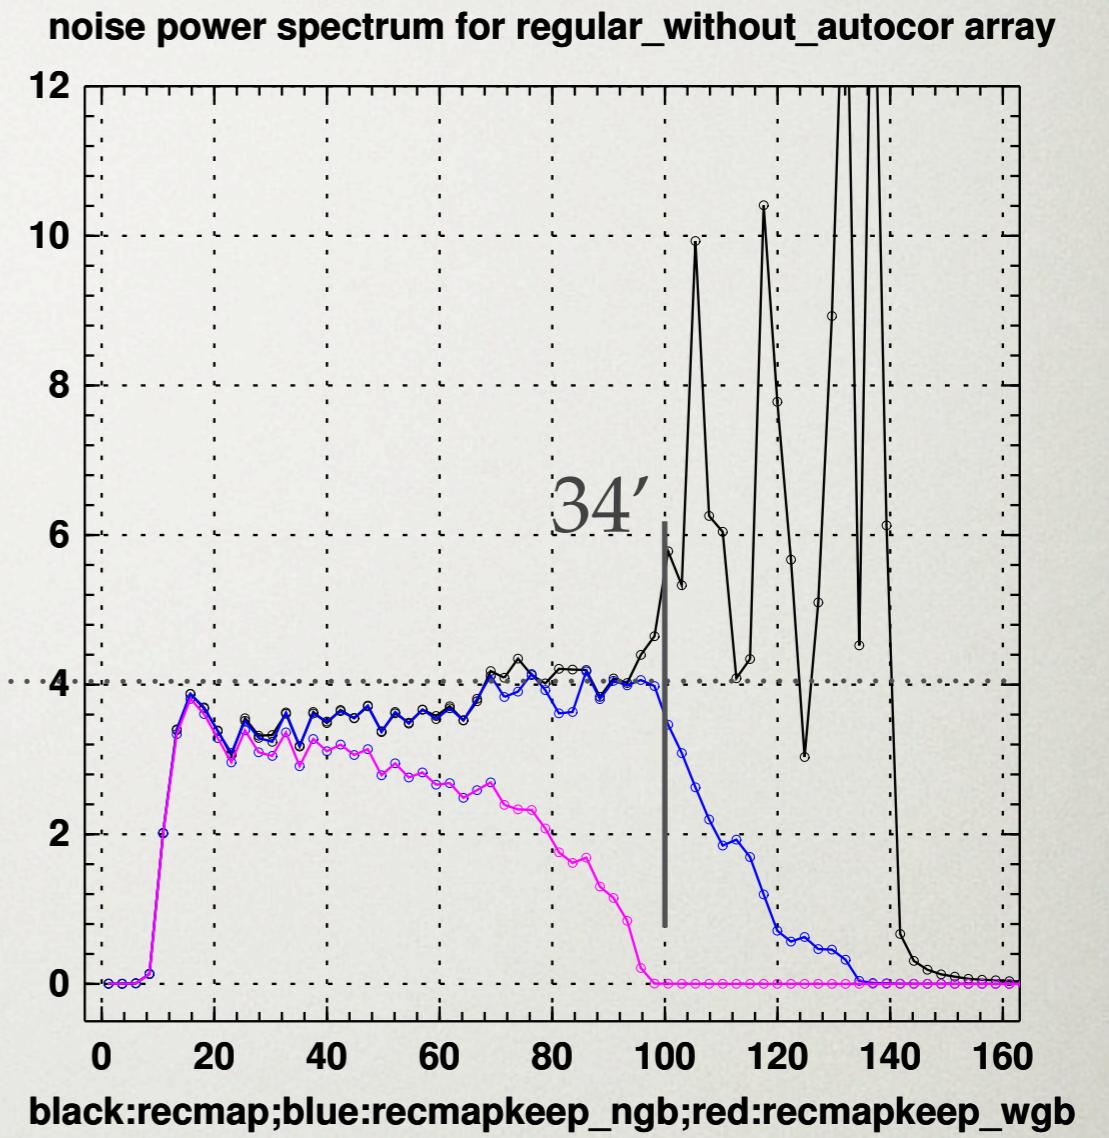

Noise power spectrum  
 Tsys = 100 K, 6 month total observation time (9  
 scans),  $\Delta\nu=1$  MHz,  $\sim 250$  ( $\alpha$ )  $\times 15$  ( $\delta$ )  $\sim 3700$  deg<sup>2</sup>  
 covered (latitude  $\sim 45$  deg)

# Regular array (a) with autocorrelation

# Regular array (a) without autocorrelation

Noise power spectrum  
regular array, with and without  
autocorrelation

- better sky reconstruction with more independent baselines → more uniform  $(u,v)$  plane coverage, better isotropy of the synthesized beam
- Possibility to optimize the beam, decreasing frequency dependency using weights on the reconstructed  $(u,v)$  plane
- Better reconstruction when increasing the number of  $\delta$  scans (over the same sky area), without noise penalty
- Choice between (b)-circular or (c)-irregular configuration ?
