

SlipStream: Deployments

C. Loomis (CNRS/LAL & SixSq)

9 December 2014

Orsay, France

Deployments

- Building applications and describing their deployments is usually handled by a system administrator and/or developer.
- SlipStream provides the ability to describe VM images in a cloud-independent way and to group nodes into a complete system.

Simple Time Server Deployment

- The deployment will consist of two nodes:
 - Time Server
 - Simple service that serves a web page with the current time.
 - Authentication Proxy
 - Proxy for time server that adds basic HTTP authentication to the system.

Create Root Project

- Create a root project to contain all of your modules.
- Your username is a good default name.

Time Project

- Within your root project, create a “time” project to hold the modules for this tutorial.
- The process is exactly the same as for creating the root project.
- You should have a screenshot like the following after you’ve created the project.

Create Time Server Image

- Create a time server image called “time-image” to hold the configuration for the time server.
- This machine will have nginx (a web server) installed and then configured to serve a page with the current time.

Execute Reports Parameters OnVmAdd OnVmRemove

```
1 # install necessary software
2 apt-get install nginx # web server to use
3 apt-get install chkconfig # to enable service
4
5 # remove the default nginx pages
6 rm -f /etc/nginx/sites-enabled/default
7
8 # create a new site which requires a username and password
9 cat > /etc/nginx/sites-available/time <<EOF
10 server {
11     listen 80;
12     server_name localhost;
13
14     location / {
15         ssi on;
16
17         root /usr/share/nginx/tutorial;
18         index index.html index.htm;
19     }
```

Add "url.time"
output
parameter!

Try It!

- As this is a single node deployment, the image itself can be run.
- Click the “Run...” button to start an instance.
- Follow the progress and see if the service works correctly.
- If it doesn't, check the “Reports” and/or log into the machine to understand what went wrong.

Runtime Parameters

- For each deployment instance (run), there is a key-value pair database containing the runtime parameters.
- This database can be used to:
 - Pass parameters between different nodes
 - Inform the user of certain values
 - Synchronize actions between nodes

SlipStream Client Commands

<code>ss-get</code>	Retrieves a value from the database, waiting if the value has not been set.
<code>ss-set</code>	Sets the value for a given parameter.
<code>ss-random</code>	Creates a random string value and optionally sets a parameter to this value.

Special Parameters

<code>customstate</code>	Message to display for node in the SlipStream run display.
<code>hostname</code>	Automatically set by SlipStream for each of the nodes in a deployment.
<code>ss:url.service</code>	Service URL for the full deployment.
<code>url.*</code>	The value of any parameter with this name is rendered as an active link.

Create Authentication Proxy Image

- Create an authentication proxy image called “proxy-image” to hold the configuration for the proxy.
- This machine will have nginx (a web server) installed which will then proxy the web server on the time-image.
- This proxy will also require basic HTTP authentication with a username and password.

Create Deployment

- The full deployment will have one time server and one authentication proxy.
- The proxy will need the hostname of the time server.
- The proxy must publish the username and password for the valid user in SlipStream.

Overview ^

- Summary ▼
- Global ▼
- orchestrator-LAL ▼
- proxy ▼

Orchestrator

- An orchestrator handles the configuration of nodes in multi-node deployments.
- The orchestrator terminates:
 - Terminates if the deployment is not “mutable”
 - Continues if the deployment is “mutable”

Next Step

- Understanding advanced features and roadmap
