Associated

LAL (Laboratoire de l'accélérateur linéaire) is a physic laboratory in Orsay (France), 20 km away from Paris. 350 people including around 100 physicists work on many experiment in cosmology, high energy particle physics and accelerator. Several technology group such as the mechanic or the electronic group work on applications to achieve physicist expectations.

The LAL electronic group (50 people) is divided in 3 units: digital design unit, analog design unit, and automated equipment design unit. Teams are involved in many big physics experiments such as Atlas, Planck, Auger and FLC. The group can work on project from the manufacturing standard to the production and ensure maintenance.

The analog team has acquired a sharp knowledge in full-custom analog ASIC design. Its specialization is focused on low-noise high-speed front-end chip and on high-precision calibration devices. Its know-how is evolving to system-on-chip designs that embed front-end electronic, auto-trigger system, calibration devices and digital converter.

IN2P3 (Nuclear and particle physics French institute) has recently asked for a rationalization of engineering resources in microelectronic and is building competence poles. Omega is the pilot structure. 10 engineers are currently in the Omega team, ensuring the R&D of several complex chip per year to serve particle physics.

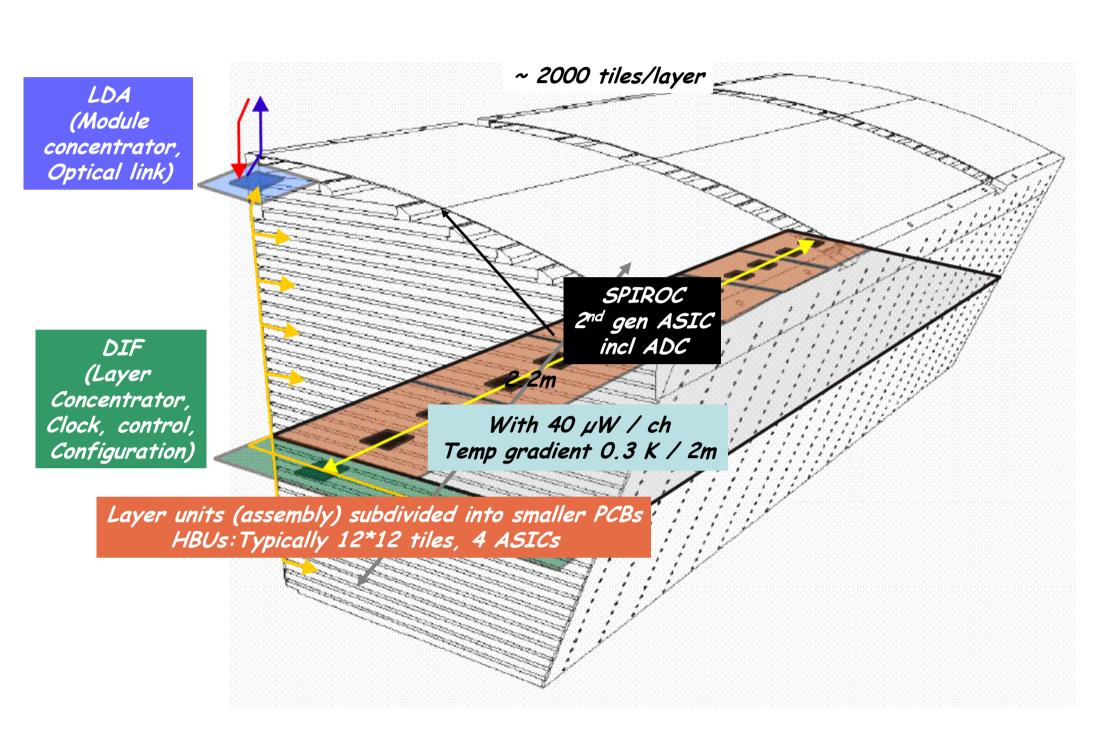

## Introduction

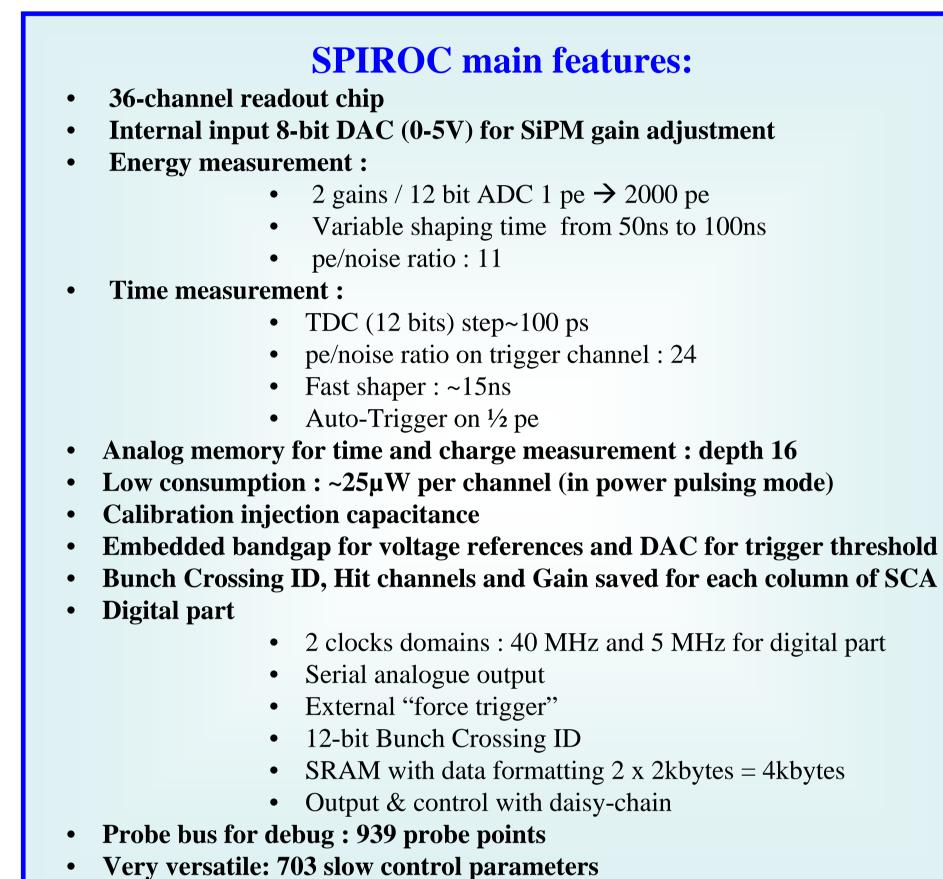

The SPIROC chip is a dedicated very front-end electronics for an ILC prototype hadronic calorimeter with SiPM readout. This ASIC is due to equip a 10,000-channel demonstrator in 2009. SPIROC is an evolution of FLC\_SiPM used for ILC AHCAL physics prototype.

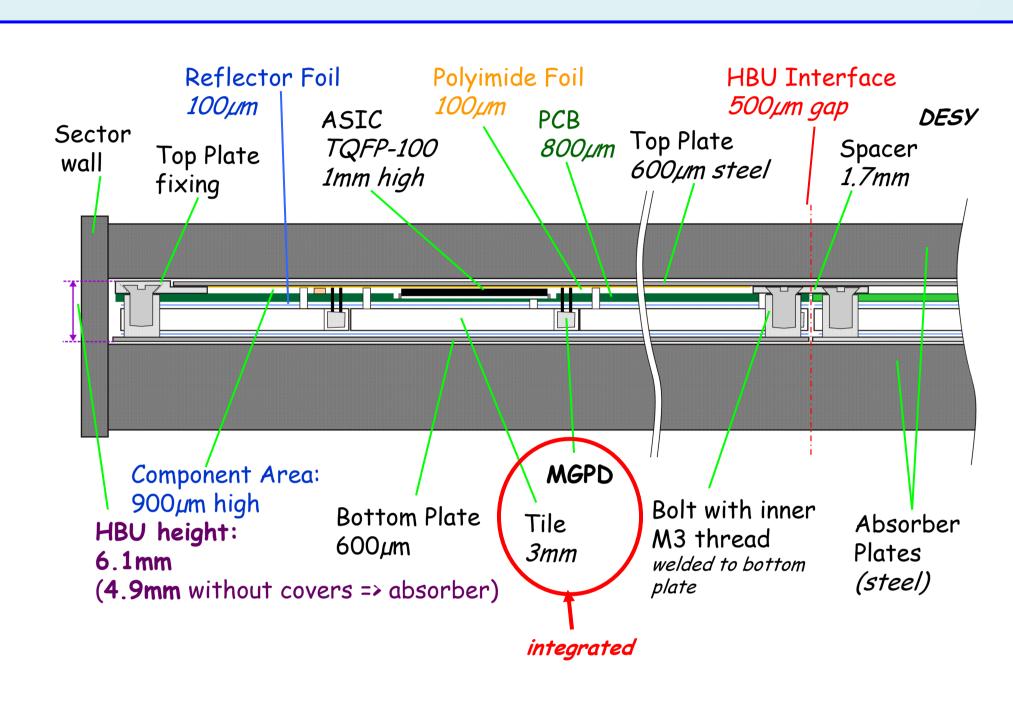

SPIROC was submitted in June 2007 and will be tested in September 2007. It embeds cutting edge features that fulfil ILC final detector requirements. It has been realized in 0.35m SiGe technology. It has been developed to match the requirements of large dynamic range, low noise, low consumption, high precision and large number of readout channels needed.

SPIROC is an auto-triggered, bi-gain, 36-channel ASIC which allows to measure on each channel the charge from one photoelectron to 2000 and the time with a 100ps accurate TDC. An analog memory array with a depth of 16 for each is used to store the time information and the charge measurement. A 12-bit Wilkinson ADC has been embedded to digitize the analog memory contents (time and charge on 2 gains). The data are then stored in a 4kbytes RAM. A very complex digital part has been integrated to manage all theses features and to transfer the data to the DAQ.

## AHCAL integrated layer design

manage all the different steps of normal working (acquisition, A/D

measure and read-out).

In parallel, trigger outputs are obtained via fast channels made of a fast shaper followed by a discriminator. The discriminator output feeds the digital part which manages the SCA.

A voltage 300ns ramp gives the analogue time measurement. The

time is stored in a 16-deep SCA when a trigger occurs.
