

Analyse Observations PAON4 - ScanA Aug 2018

Reza - 28 Août 2018

1. Description de l'analyse

2. Sources brillantes :

➡ CasA (A04,A16) , CygA (A20)

3. Sources moins brillantes:

➡ 3C380 (A10), 3C295 (A05-A06) , NGC1275/Pers.A (A19)

4. Conclusions préliminaires

- Observations PAON4 (ScanA) de Juillet-Août 2018
- Observations/gestion des acquisitions par Claude
- Réduction des données (cartes TFM, corrections de gain $g(\nu)$, $G(t)$ et phases) par Olivier
- Détermination de phases instrumentale par ajustement des franges CasA par Jean-Eric sur le transit CasA du 17 Juillet (A00)
- Analyse du 25-28/08, à partir des calibrations d'Olivier ~24 Août -
- Comparaison signaux observés et attendus à 1395 MHz (synchrotron et radio-sources) et 1420 MHz (HI Galactique + radio-sources)
- Signaux attendus calculés par map2vis à 2 fréquences, à partir d'une carte synchrotron+sources NVSS > 1 Jy (1395 MHz) et carte LAB + sources NVSS > 1 Jy (1420 MHz)
- **L'analyse des observations ne comprend aucun filtrage/nettoyage ni en temps, ni en fréquence**
- Les observations des voies H sont simplement moyennées sur une bande de 10 MHz autour de 1395 MHz et une bande de 1.2 MHz autour de 1420.4 MHz

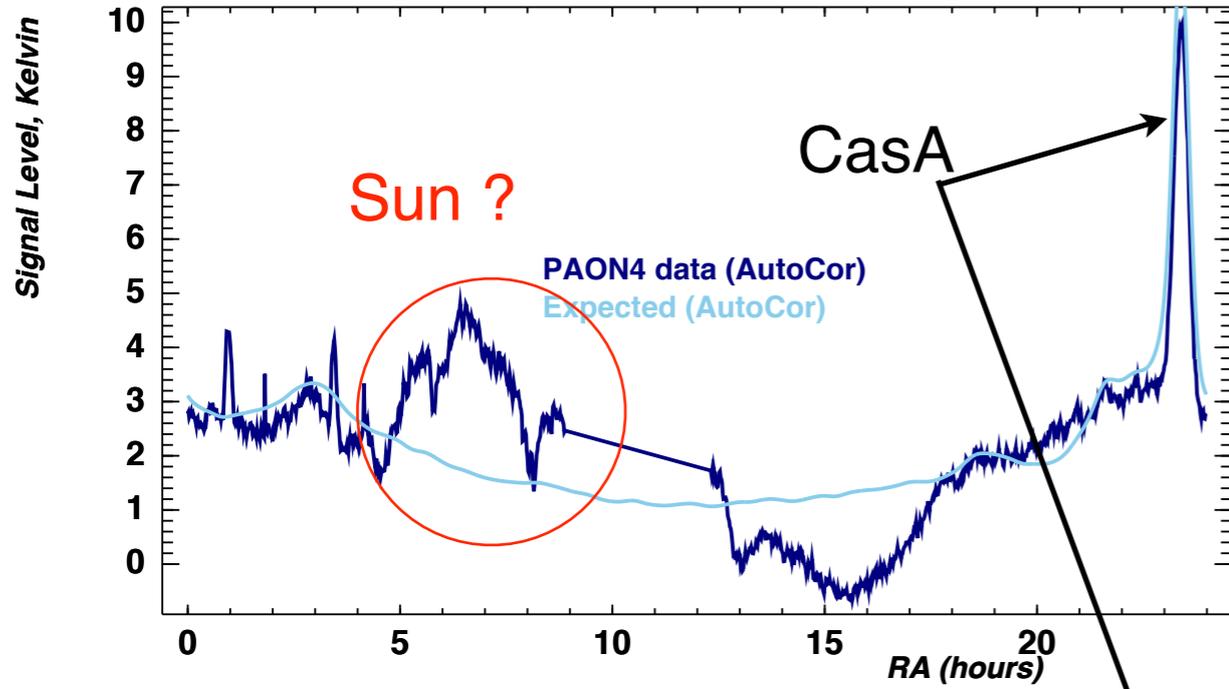

- Le signal d'autocorrélation (AC) correspond simplement à la moyenne des autocorrélations des 4 voies H
- Après correction de gain dépendant du temps/température par Olivier, les signaux d'autocorrélation sont autour de l'unité
- Un facteur de conversion en température ~ 110 a été déterminé à l'oeil en comparant le signal AC observé et attendu à 1420 MHz, ainsi qu'un niveau de bruit ~ 0.98 , correspondant donc à $T_{\text{sys}} \sim 107$ K
- Les signaux des 6 cross-corrélations (CX) H-H ont simplement été multipliés par le facteur de conversion 110
- $AC \rightarrow (AC - 0.98) \times 110$ en Kelvin ; $CX \rightarrow CX \times 110$ en Kelvin
- J'ai calculé les signaux attendus à 1420 MHz en sommant les cartes LAB sur une largeur de bande ~ 1.2 MHz, alors que les structures HI varient violemment sur ces bandes de ~ 1.2 MHz
- On s'attend donc à des différences relativement importantes entre signaux observés et ceux calculés en supposant que toute l'émission se fait à la fréquence centrale de 1420.4 MHz

Sources brillantes

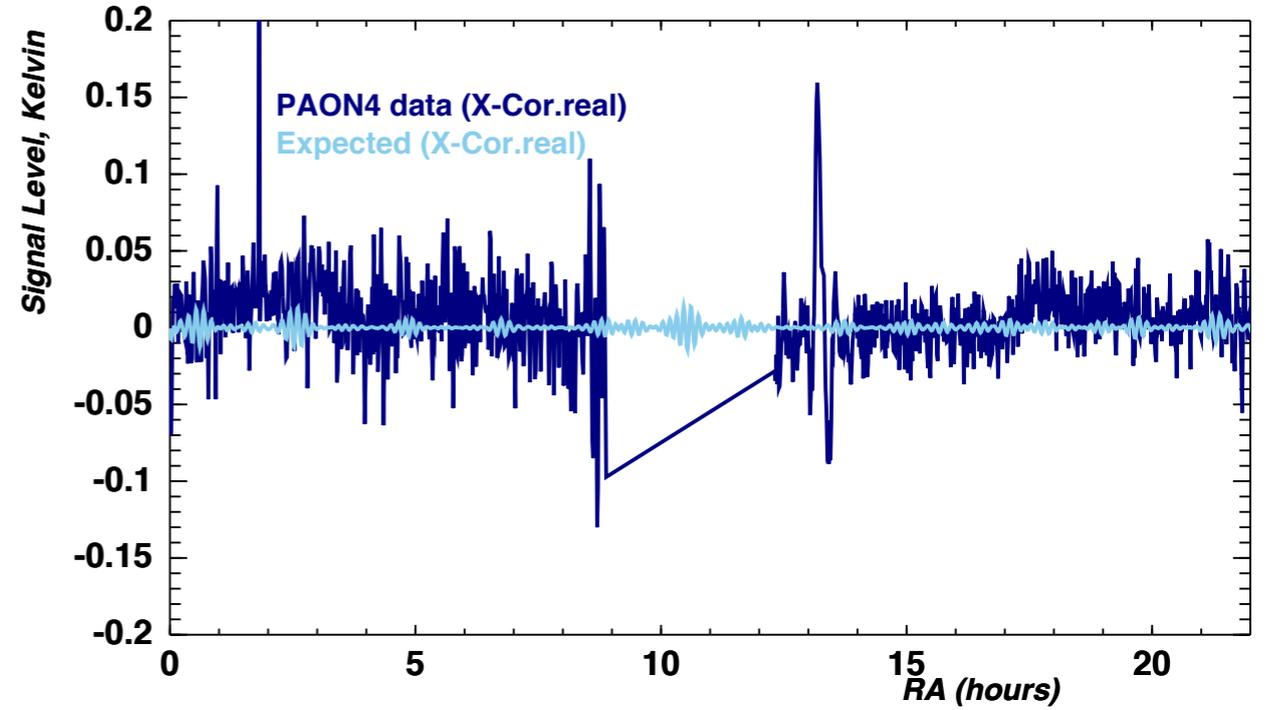

CasA ($\alpha=23\text{h}23.5$, $\delta=58\text{d}48'$) : **A04** **A16**

Scan A04 du 21/07 Elev=11.4 - Declinaison de CasA

Conclusions préliminaires

- Résultats presque conformes aux attentes
- Franges sources brillantes OK ,
- $T_{\text{Sys}} \sim 100\text{-}105\text{ K}$, mais il reste du bruit corrélé et des RFI, diminuant de fait la sensibilité de l'instrument
- Effet du soleil, ($\sim 2\text{K}\text{-}3\text{K}$) autour de midi solaire
- D'autres RFI, probablement les satellites polluent également le signal
- On constate aussi un niveau moyen des visibilités (re, im) qui n'est pas à zéro. S'agit-il d'un effet du bruit corrélé ?
- Il faudra mettre en place un filtrage/masquage temps-fréquence
- Signaux des sources $\sim 20\text{ Jy}$ assez bien visible, mais il faudra améliorer la sensibilité de PAON4
- Il serait probablement utile de refaire des scans, au moins autour d'une de sources $\sim 20\text{ Jy}$...
