Electro-association of two ultracold dipolar molecules into a tetramer

vendredi 7 juillet 2023 10:10 (20 minutes)

We explore the possibility of electro-association of two ultracold dipolar molecules into a long-range tetramer state, called a “field linked state”. These particular states have been predicted in 2003 [1] in a static electric field and more recently in a microwave [2]. Such states have been confirmed by a recent experiment [3] in the resonances of ultracold molecular scattering.

We discuss the experimental feasibility of the process in terms of the adequate electric field ramp of a microwave to apply, different decay lifetimes, and in terms of the initial population starting with either thermal or quantum degenerate gases. The process shares a lot in common with magneto-association for which one can associate two ultracold atoms into a long-range diatomic molecule using a ramp of magnetic field [4]. This can be a primary step to form ground-state tetramers [5].
